

L2 Metro Lima: TBM excavation
design (Settlement – PAT) & construction
follow up

ETH – Zurich,
December 2022

Agenda

1. Overview L2 Metro Lima
2. Geotechnical context
3. Settlements & pressures definition
4. Soil conditioning
5. Construction follow up

Overview

Metro Lima General Layout

Trenes
Línea 2

Metro de Lima y Callao

Simbología	
●	Estaciones
○	Estación de Interconexión
⊕	Estación Intermodal
---	Ruta de metro proyectada
—	Ruta de metro operativa

Legend:

	37 km	Line 1: operating
	27 km	Line 2: under construction
	31.50 km	Line 3: design stage
	26 km	Line 4: design stage
	13.90 km	Line 5: under evaluation
	30 km	Line 6: under evaluation

General information of the Line 2:

First underground fully automated metro in Peru' (Vmax = 90km/h)

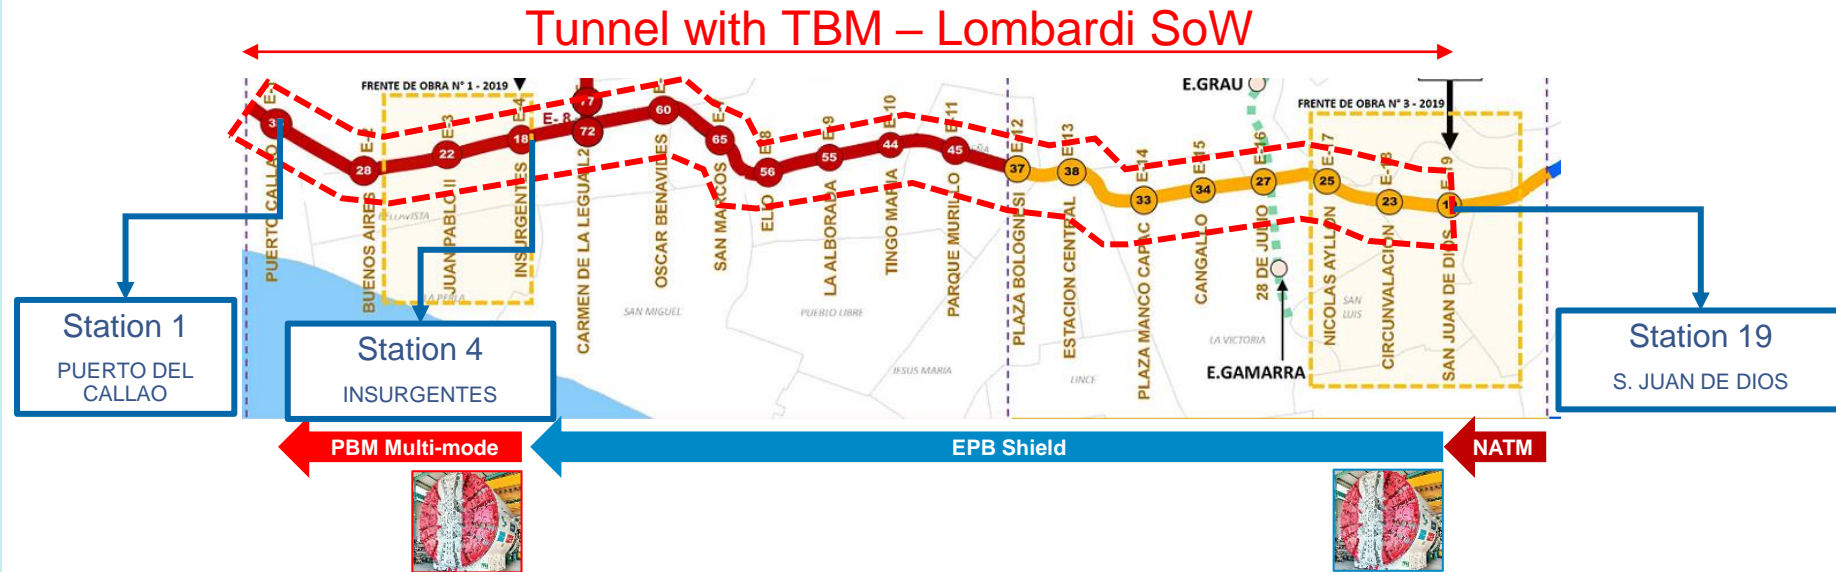

~ 660'000 passengers per day

Total cost > \$ 3 Billion

Main benefit → Environmental sustainability (strong reduction of vehicular traffic)

Metro Lima

Line 2 – TBM section

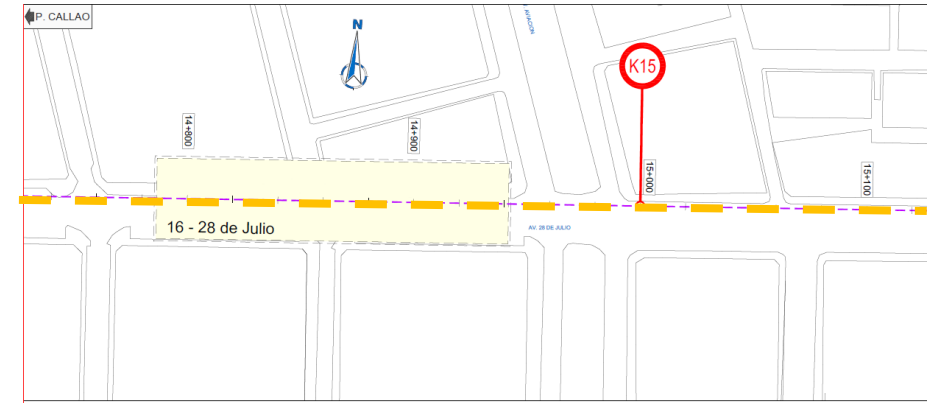

Key facts (Line 2, TBM section):

- 17.3km of mechanized excavation
- 1 TBM - EPB Shield
- 1 TBM - Multi-mode (EPB / Slurry)
- Excavation diameter $\Phi_{exc} = \sim 10.3 \text{ m}$
- Max. Overburden = 19.5 m
- Min. Overburden = 4.5 m
- 19 Stations + 18 Ventilation shafts

Metro Lima

Line 2 - Urban context

Alignment in a high-density urban area, under the road

Lima Geotechnical context

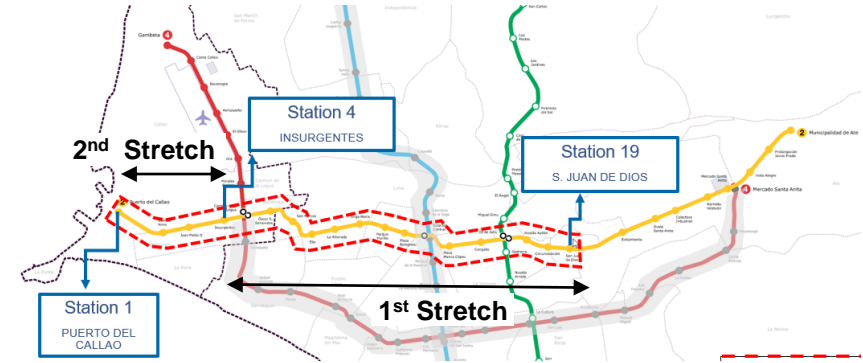

Gravel with cobbles

Geotechnical context

Geological conditions

R	Anthropic fill
CL/ML	Alluvial deposit: Clay / Silt
SM	Silty sand
GP	Gravel poorly graded

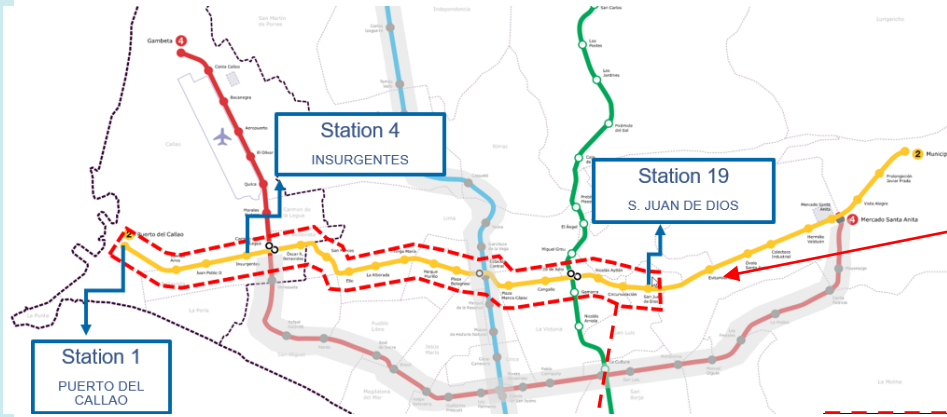

1st Stretch - Typical condition from ST19 to ST4

2nd Stretch - Typical condition from ST4 to ST1

Geotechnical context Excavation face

Face condition NATM

Face condition TBM tunnel

Soil condition after TBM excavation

Settlements & pressures definition and building damage estimation

Methodology

1) First stage preliminary: analytical assessment FF

$S_v < 10 \text{ mm}$
 $\Delta/L(\text{mm/m}) < 1/500$

Yes

Green field settlement estimation

(Peck, 1969; O'Reilly and New, 1982; Attewel & Woodman, 1982; Moh & Hwang, 1996, Burland & Wroth, 1974)

No

2) Second stage: analytical assessment simplified interaction

ϵ_{max}
 $\Delta/L(\text{mm/m}) < 1/500$

Yes

Building deflection and horizontal strain considering building stiffness

(Potts & Addenbrooke, 1997)

No

3) Third stage: detailed evaluation

ϵ_{max}
 $\Delta/L(\text{mm/m}) < 1/500$

Yes

Building deflection and horizontal strain by numerical calculations

No

Protective measures

Negligible to slight damage

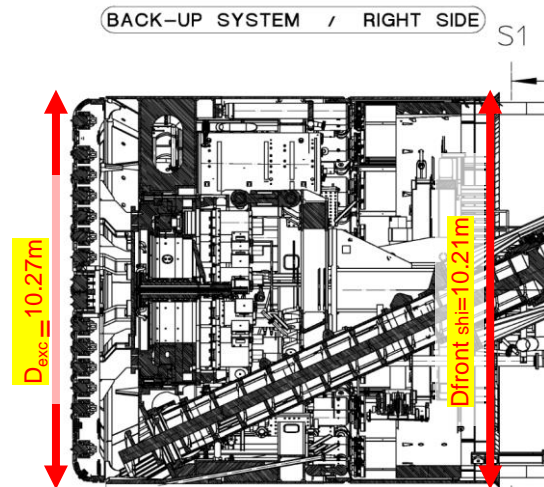

Volume loss definition

The ratio of the volume of the surface settlement trough to the excavated face area usually expressed as percentage.

Volume loss procedure definition

- 1 Geometrical volume loss: difference between excavation diameter and tail shield diameter (conicity of shield).
- 2 Evaluation of efficiency: according to N. Ruse & H. Schwarz graph
- 3 Risk analysis: evaluation of the key factor can generate volume loss (face pressure, grout pressure, weight of excavated material, grout volume injection...) and definition of the mitigation measures (excavation control, topographic control, quality system for excavation procedure...)
- 4 Evaluation of the increment on the efficiency of the excavation through a risk analysis
- 5 Definition of Volume loss for calculation

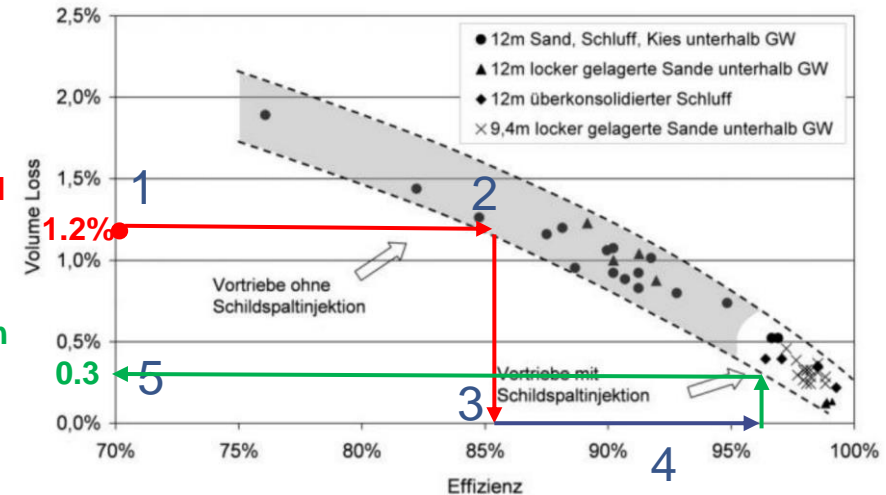

Geometrical VL

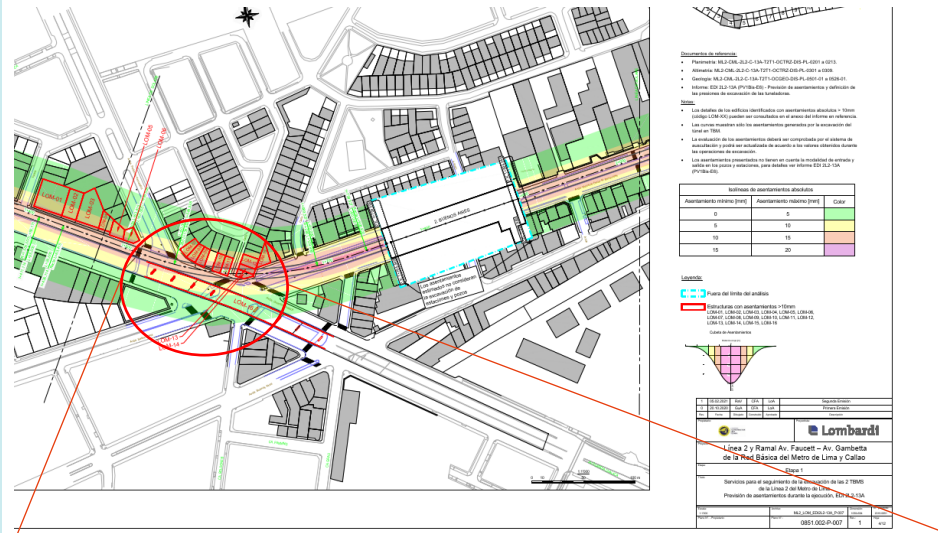

Calculation VL

Sección	Diámetro	Área [m ²]	% respecto al área de excavación	% volumen perdido
Excavación	10.27	82.84	100	0
Escudo delantero	10.21	81.87	98.8	1.2 ●

N. Ruse & H. Schwarz (2012)

Analytical assessment: results of settlement evaluation and damage estimation

Settlements

Isoleínas de asentamientos absolutos		
Asentamiento mínimo [mm]	Asentamiento máximo [mm]	Color
0	5	Verde
5	10	Amarillo
10	15	Naranja
15	20	Púrpura

Admissible level of deformation

Categoría de daño	Índice de vulnerabilidad de la estructura, I_v				
	Despreciable	Bajo	Ligero	Moderado	Alto
	$0 < I_v < 20$	$20 < I_v < 40$	$40 < I_v < 60$	$60 < I_v < 80$	$80 < I_v < 100$
	Factor de reducción, F_R				
	$F_R=1.0$	$F_R=1.25$	$F_R=1.5$	$F_R=1.75$	$F_R=2.0$
	Deformación límite por tracción, ϵ_{lim} [%]				
0	$\epsilon_{lim} < 0.05$	$\epsilon_{lim} < 0.04$	$\epsilon_{lim} < 0.033$	$\epsilon_{lim} < 0.029$	$\epsilon_{lim} < 0.025$
1	$0.05 < \epsilon_{lim} < 0.075$	$0.04 < \epsilon_{lim} < 0.06$	$0.033 < \epsilon_{lim} < 0.05$	$0.029 < \epsilon_{lim} < 0.043$	$0.025 < \epsilon_{lim} < 0.038$
2	$0.075 < \epsilon_{lim} < 0.15$	$0.06 < \epsilon_{lim} < 0.12$	$0.05 < \epsilon_{lim} < 0.1$	$0.043 < \epsilon_{lim} < 0.086$	$0.038 < \epsilon_{lim} < 0.075$
3	$0.15 < \epsilon_{lim} < 0.3$	$0.12 < \epsilon_{lim} < 0.24$	$0.1 < \epsilon_{lim} < 0.2$	$0.086 < \epsilon_{lim} < 0.171$	$0.075 < \epsilon_{lim} < 0.15$
4 y 5	$0.3 < \epsilon_{lim}$	$0.24 < \epsilon_{lim}$	$0.2 < \epsilon_{lim}$	$0.171 < \epsilon_{lim}$	$0.15 < \epsilon_{lim}$

Damage category

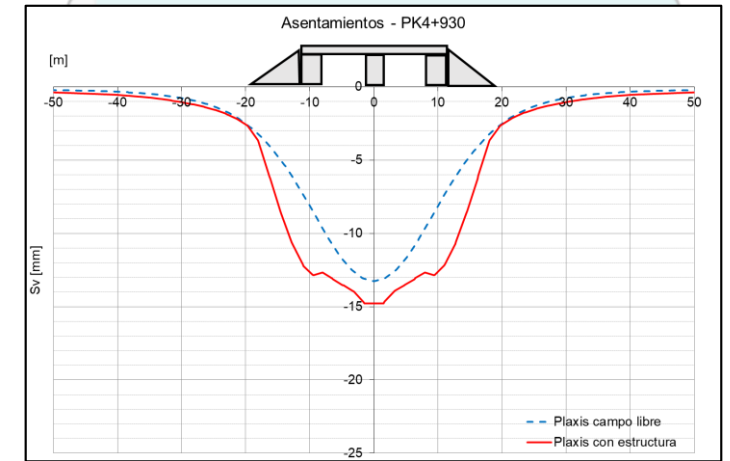

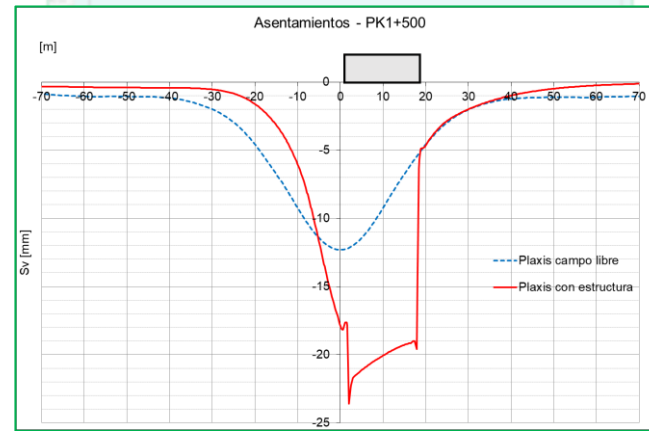

Índice vulnerabilidad [-]	ϵ_{max} [%]	Categoría de daño
0-20	0.07	1
20-40	0.06	2
20-40	0.06	2
20-40	0.11	2

Numerical Models

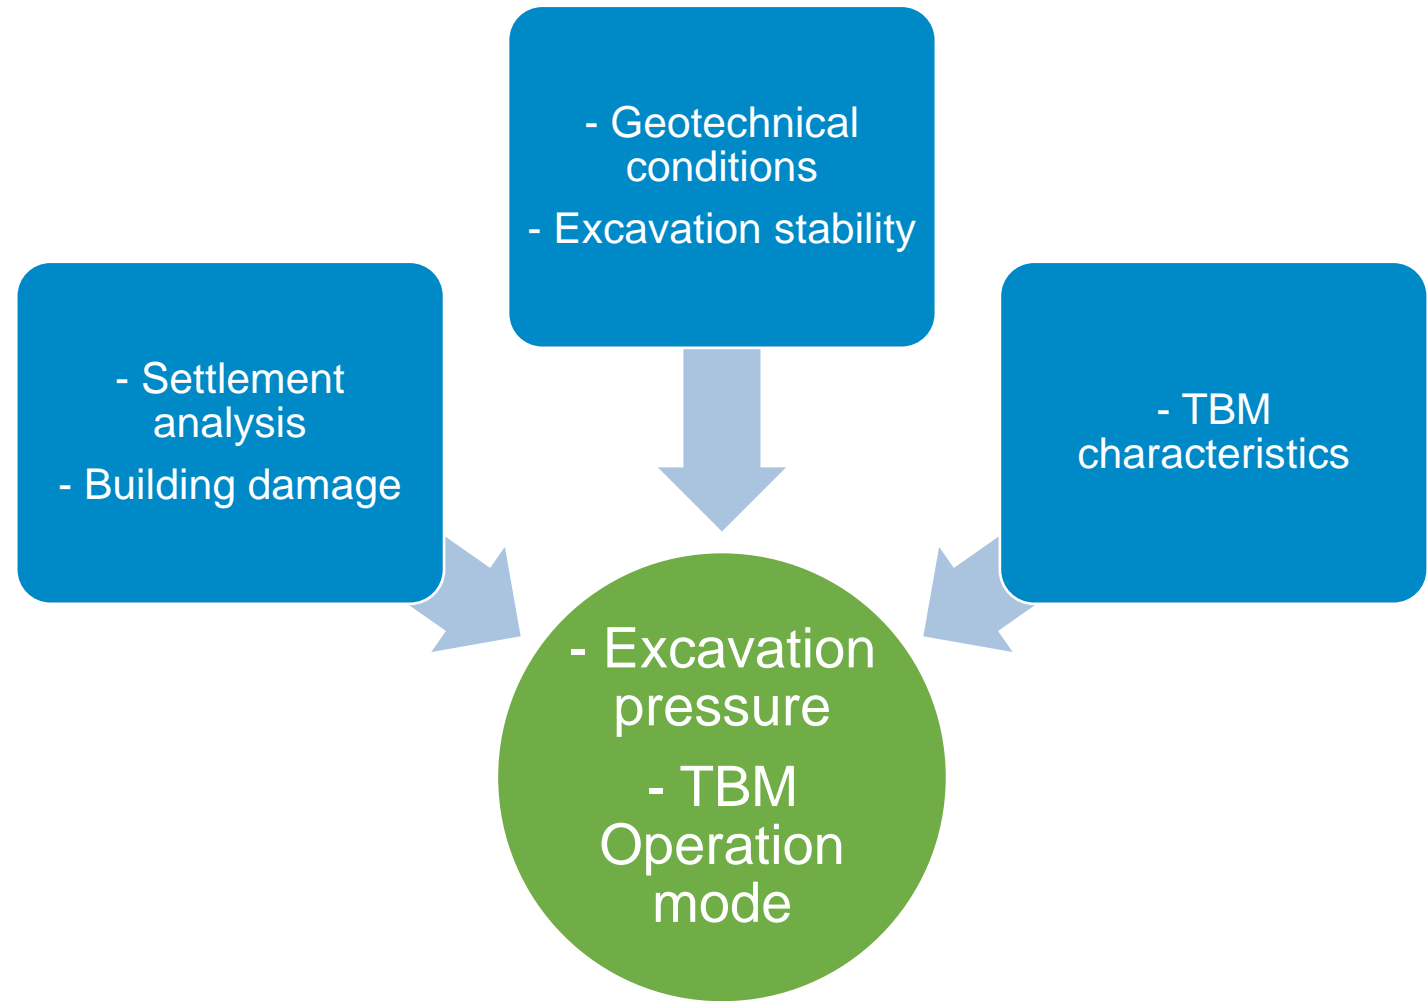

PK	Estructura	Δ/L [mm/m]	ϵ_h [%]

Soil Conditioning for EPB excavation

Soil Conditioning laboratory test

Laboratory test carried out:

– The half-life time of a foam:

defined as the time required by a foam to drain 50% of the weight of the initial conditioning liquid used in foam generation (EFNARC, 2005)

– The fall cone test:

measures the penetration h_f of a cone dropped under its own weight after being released from the standardized support

– The pull-out test:

represents a family of widespread systems for measuring the adhesion between a metallic element and the soil.

– Slump test and flow table test:

the slump test is carried out using the Abrams cone, the flow table test or flow test is a method to determine the consistency of specimens.

Figure 4. Pull-out plate test laboratory apparatus.

Figure 1. Half-time life test apparatus.

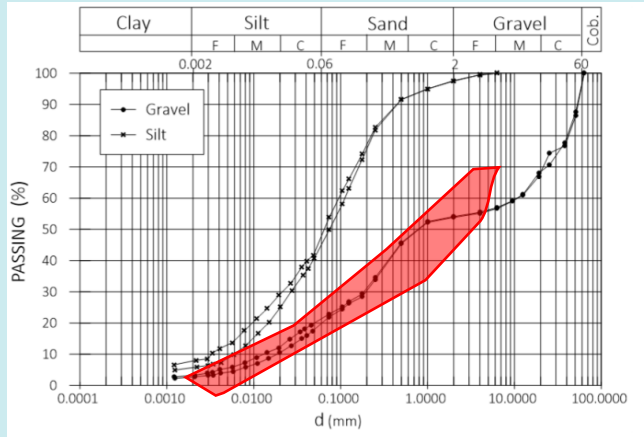

Figure 3. Fall cone test apparatus.

Figure 5. Slump test (left) and flow table test (right) apparatuses.

Soil conditioning Gravel

Laboratory test results carried out with two foaming agents: CLB F5/M (CONDAT) and ACTISOYL 20W (TNL18)

The samples have been conditioned with different dosages, prepared at a natural water content $w_n=10\%$. The concentration of the foam C_f was set as fixed parameter and equal to 2%. The foam expansion ratio FER was chosen based on the granulometry between 12÷15. The added water w_{add} and foam injection ratio FIR were then adjusted to obtain a good soil paste, according to slump test, flow table test and visual inspection. Starting from those parameters, the treatment ratio TR was calculated.

FER: foam expansion ratio. Ratio between the volume of the foam and the volume of foaming solution used.

FIR: foam injection ratio. Ratio between the volume of foam injected and the volume of soil.

C_f: concentration factor of the foam. Percentage ratio between the weight of the foaming agent and the total weight of the foaming solution.

TR: treatment ratio. Volume of foaming agent used to treat a unit volume of soil.

w_n: initial water content of the soil.

w_{add}: amount of water added for conditioning (% on the weight of the soil).

w_{cond}: water content of the conditioned soil

Excavation parameters control

Settlements control

Asentamiento y avance

TBM excavation control (face pressure – tail void injection and volume pressure – weight of excavated material)

Asentamiento y avance

Presión al Frente S7 (kPa)

Conclusion

_Definition of settlements and excavation pressures is an iterative process (with a continuous control and update)

_With a correct definition of the soil conditioning is possible to achieve the requested:

_stability of the face

_level of settlements (with a mitigation of the risk of damage)

_rate of the advance of tunnel excavation

_The strict control and continuous analysis of excavation and monitoring data are necessary to ensure that TBM advancement takes place with the requested level of safety

_After approx. 2.5 km of excavation of TBM 1 and 1km of excavation of TBM2 the settlements assessment has been respected using the face pressure and other machine parameters defined in the design stage
