## Why?

- **Nitrous oxide (N<sub>2</sub>O)** is the third most important greenhouse gas.
- ~70% of anthropogenic N<sub>2</sub>O emissions are attributed to **agriculture** due to the use of nitrogen (N) fertilizers.
- Limited understanding of NO<sub>2</sub> drivers in croplands
- **What can farmers do to reduce the NO<sub>2</sub> footprint of crop production?**

## Results!

- **CO<sub>2</sub> flux** (Net Ecosystem Exchange, NEE) ranked as the **2<sup>nd</sup> most important driver** after N fertilization [Fig. 1]
- **Increased CO<sub>2</sub> uptake limits N<sub>2</sub>O emissions** [Fig. 2]

Fig. 1. Features ranked by their importance in the model. The x-axis shows SHAP values: positive values indicate that the feature increases N<sub>2</sub>O emissions, while negative values suggest a decrease. The color gradient represents the feature values.

## How?

### Data collection:

- **Eddy covariance station** → N<sub>2</sub>O, CO<sub>2</sub>, H<sub>2</sub>O and CH<sub>4</sub> fluxes
- **Meteo station** → >30 environmental variables
- **Manual measurements** → crop growth and soil N content

### Statistical analysis:

- **Random forest** supervised machine learning
- **SHAP** (Shapely Additive exPlanations) explanation of machine learning model predictions

Fig. 2. SHAP dependence plot showing the impact of CO<sub>2</sub> flux (negative values indicate uptake) on N<sub>2</sub>O emissions. The x-axis represents the CO<sub>2</sub> flux, and the y-axis shows the SHAP value of the CO<sub>2</sub> flux. The color gradient reflects the measured N<sub>2</sub>O flux.

## Discussion and conclusions
