

Concepts of Object-Oriented Programming

Prof. Dr. Peter Müller

Chair of Programming Methodology

Exercises 4: Components

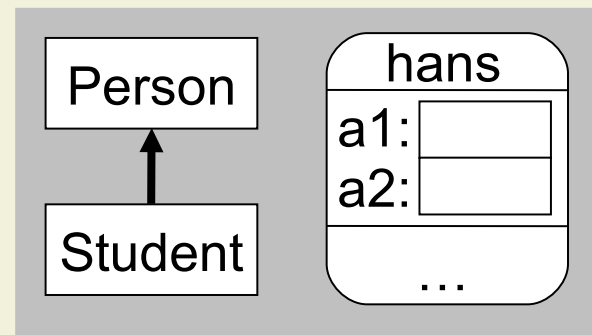

Eidgenössische Technische Hochschule Zürich
Swiss Federal Institute of Technology Zurich

Main Forms of Reuse “in the Small”

■ Inheritance

- Subclassing establishes “**is-a**” relation
- Enables subtype **polymorphism**
- Only **one object** at runtime

■ Aggregation

- Establishes “**has-a**” relation
- **No subtyping** in general
- **Two objects** at runtime

Exercise 4.5 – Set

```
public void add( Object o ) {  
    assert true : "Any state allowed."; // pre  
    ...  
    assert isElem( o ) : "Element not  
    successfully inserted!"; // post  
}
```

```
public void remove( Object o ) {  
    assert isElem( o ) : "Element must be  
    contained in the set!"; // pre  
    ...  
    assert !isElem( o ) : "Element was not  
    removed successfully!"; // post  
}
```

Exercise 4.5 – Set

```
public boolean isElem( Object o ) {  
    assert true :  
        "Any state allowed."; // pre  
    ...  
}
```

```
public int size() {  
    assert true : "Any state allowed."; // pre  
    ...  
    assert s == set_impl.size() :  
        "Inconsistent size value!"; // post  
}
```

Exercise 4.5 – BoundedSet

```
public void add( Object o ) {  
    assert size() < max : "Size >= max!"; // pre  
    ...  
    assert isElem( o ) : "Element not successfully  
    inserted!"; // post  
    assert size() <= max : "Size > max!"; // invariant  
}
```

```
public void remove( Object o ) {  
    assert isElem( o ) : "Element must be contained in  
    the set!"; // pre  
    ...  
    assert !isElem( o ) : "Element was not removed  
    successfully!"; // post  
    assert size() <= max : "Size > max!"; // invariant  
}
```

Exercise 4.5 – BoundedSet

```
public boolean isElem( Object o ) {  
    assert true : "Any state allowed."; // pre  
    ...  
    assert size() <= max : "Size > max!"; // invariant  
}  
  
public int size() {  
    assert true : "Any state allowed."; // pre  
    ...  
    assert s == set_impl.size() : "Inconsistent size  
value!"; // post  
    assert s <= max : "Size > max!"; // invariant  
}
```

Exercise 4.6

- ObjectList:

```
// requires type( obj ) <= Object  
void insert( Object obj ) ...
```

- IntegerList:

```
// requires type( obj ) <= Integer  
void insert( Object obj ) ...
```

➔ IntegerList no subtype of ObjectList,
because the precondition gets stronger!

Exercise 4.6

- So should `ObjectList` be a subclass of `IntegerList`?
- Contract of the `insert` method would get weaker!
- Integerlist:

```
// ensures type( res ) <= Integer  
Object get( int idx ) ...
```

- ObjectList:

```
// ensures type( res ) <= Object  
Object get( int idx ) ...
```

➔ Postcondition gets weaker, which is not allowed!

Exercise 4.7

- `List<Object>` **substituted method signatures:**
`void insert(Object obj)`
`Object get(int idx)`
- `List<Integer>` **substituted method signatures:**
`void insert(Integer obj)`
`Integer get(int idx)`
- As before, the two possible subtype relationships would violate behavioral subtyping
- Java forbids subtype
- Eiffel does not check and might create a CAT call

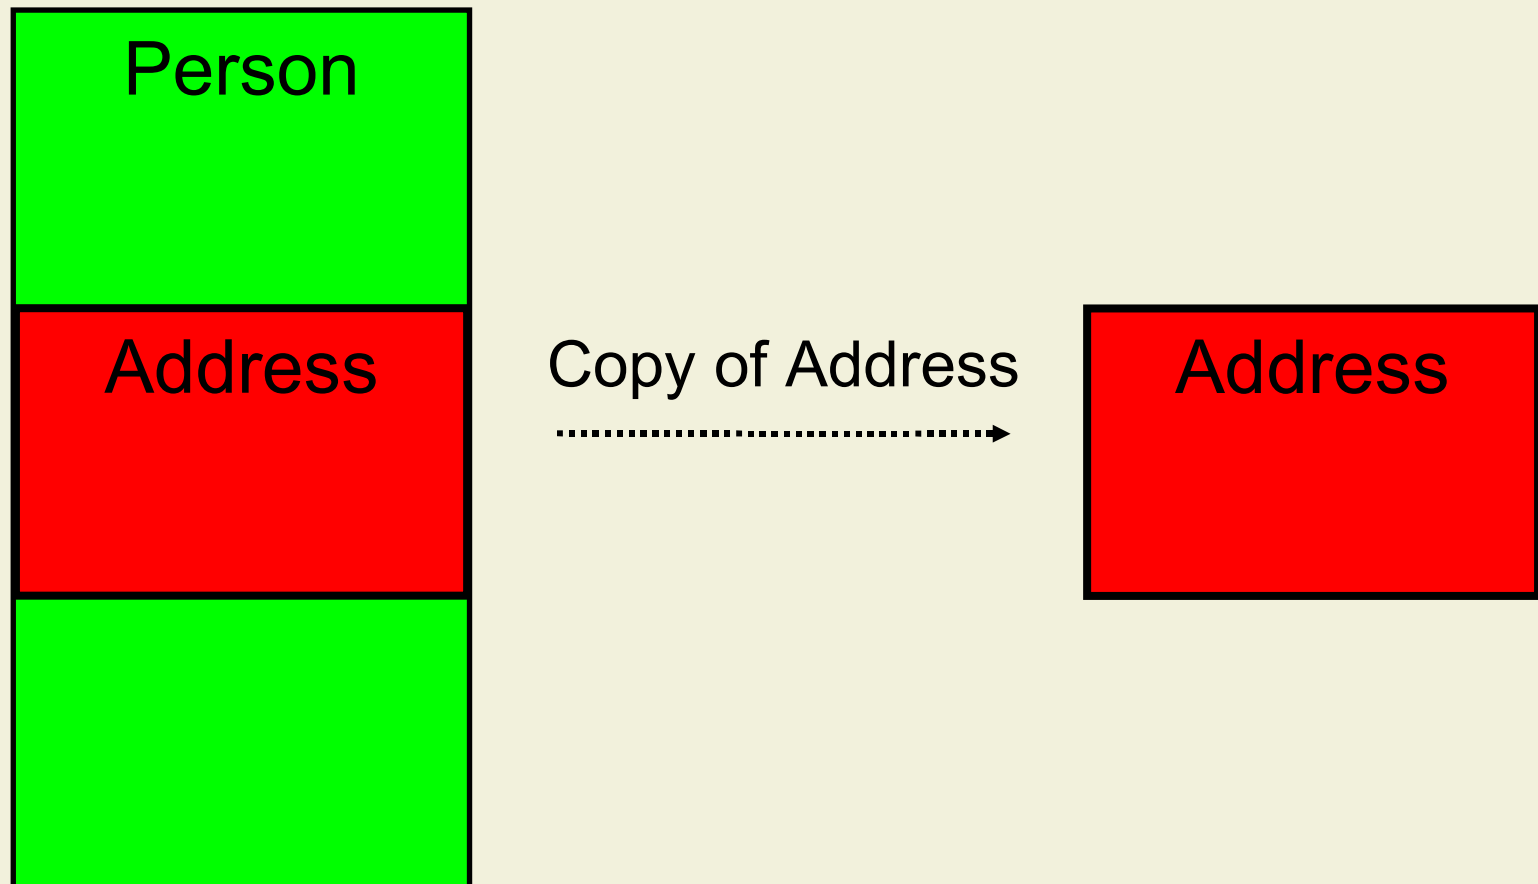

Solution in Scala: Variance Annotations

```
class Stack[+A] {  
  def push[B >: A] (elem: B) : Stack[B] =  
    new Stack[B] {  
      override def top: B = elem  
      override def pop: Stack[B] = Stack.this  
      override def toString() =  
        elem.toString() + " " +  
        Stack.this.toString()  
    }  
  def top: A = error("no element on stack")  
  def pop: Stack[A] = error("no element on stack")  
  override def toString() = ""  
}
```

Aggregation

- Java always stores references to other objects
- In e.g. C++ the developer has the choice to either safe a reference to the aggregate object or include it in its own body
- “has-a” and “part-of” aggregation
- Let’s look at the pros and cons a bit
- `Address` and `FullAddress` store information
- `Address > FullAddress`
- `A Person` uses an `Address` object to store its information

Part-of Aggregation

Part-of Aggregation in C++

```
class Person {  
    Person(...) { ... }  
  
    void setAddress( const Address &a ) {  
        addr = a; }  
    Address getAddress() {  
        return addr; }  
  
    Address addr;  
};
```

← Copy-Constructor of Address is called!

←

Problem with Part-of Aggregation

```
Person p( ... );
```

```
FullAddress a( ... );
```

```
cout << "Person after construction: " << endl;
```

```
cout << p.getAddress().getID() << endl;
```

```
p.setAddress( a );
```

Only the Address information is copied!
System not extendible by subtyping!

```
cout << "Person after asssigning a  
FullAddress: " << endl;
```

```
cout << p.getAddress().getID() << endl;
```

Advantages of Part-of Aggregation

- It is a bit harder for the programmer to create unwanted aliases to the aggregate
- It might be more efficient

Has-a Aggregation

Has-a Aggregation in C++ (Always in Java)

```
class Person {
```

```
    Person(...) { addr = new Address (...); }
```

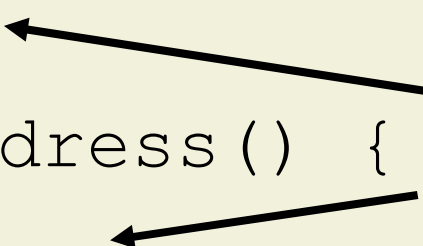

```
    void setAddress( Address *a ) {
```

```
        addr = a; }
```

```
    Address *getAddress() {
```

```
        return addr; }
```

Reference to Address
is stored/returned!

```
    Address *addr;
```

```
};
```

Pros & Cons of Has-a Aggregation

- The aggregate can be exchanged at runtime with a different object, even of a different subtype
- Dynamic change of behavior possible
- Recursive data structures like linked-lists only possible with has-a aggregation
- Problems with multiple references to the same object difficult to handle

Another Casting Example

```
interface I1 {}           interface I2 {}  
interface I3 extends I1, I2 {}
```

```
class C1 implements I3 {}  
class C2 implements I2 {}
```

```
class Conv {  
    public static void main( String argv[] ) {  
1      C1 c1 = new C1();  
2      I2 i2 = (I2) c1;  
3      String s = (String) i2;  
4      C2 c2 = (C2) i2;  
5      I1 i1 = (I1) i2;  
6      I3 i3 = new I3();  
7      i1 = (I1) c1;  
    }  
}
```

Compilation Error!
ClassCastException

Compilation Error!

What's this programs output?

```
class K {  
    K() { System.out.println("K"); }  
  
    public static void main(String[] args) { new M(3); }  
}  
  
class L extends K {  
    L() { System.out.println("L"); }  
}  
  
class M extends L {  
    M(int p) { System.out.println("M"); }  
}
```

What's this programs output?

```
class K {  
    K(int p) { System.out.println("K"); }  
  
    public static void main(String[] args) { new M(3); }  
}  
  
class L extends K {  
    L(int p) { System.out.println("L"); }  
}  
  
class M extends L {  
    M(int p) { System.out.println("M"); }  
}
```

Compilation Error!

Dynamic Type Information

```
class A {  
    void m() {  
        if( this instanceof A )  
            System.out.println("I'm an A!");  
        if( this instanceof B )  
            System.out.println("I'm a B!");  
    }  
}  
  
class B extends A {  
    public static void main(String[] args) {  
        A a = new B();  
        a.m();  
    }  
}
```

I'm an A!
I'm a B!

Object Comparison

```
class D {  
    private int x;  
    public D( int p ) { x = p; }  
  
    public boolean equals( Object o ) {  
        if( o instanceof D ) {  
            return ((D)o).x == this.x;  
        }  
        return false;  
    }  
}
```

Questions?
