Reuse

■ Inheritance

- Only **one object** at run time
- Relation is fixed at compile time
- Often coupled with subtyping

■ Aggregation

- Establishes “**has-a**” relation
- **Two objects** at run time
- Relation can change at run time
- **No subtyping** in general

3. Inheritance

3.1 Inheritance and Subtyping

3.2 Dynamic Method Binding

3.3 Multiple Inheritance

3.4 Linearization

Inheritance versus Subtyping

- **Subtyping** expresses **classification**
 - Substitution principle
 - Subtype polymorphism
- **Inheritance** is a means of **code reuse**
 - Specialization
- Inheritance is **usually coupled** with subtyping
 - Inheritance of all methods leads to structural subtypes
 - Coupling is also a useful default for nominal subtyping
- Terminology: **Subclassing** = Subtyping + Inheritance

Simulation of Subclassing with Delegation

- Subclassing can be simulated by a combination of subtyping and aggregation
 - Useful in languages with single inheritance
- OO-programming can do without inheritance, but not without subtyping
- Inheritance is **not a core concept**

Simulation of Subclassing: Example

```
interface Person {  
    void print( );  
}
```

```
interface Student extends Person {  
    int getRegNum( );  
}
```

Subtyping

```
class PersonImpl  
    implements Person {  
    String name;  
    void print( ) { ... }  
    PersonImpl( String n ) { name = n; }  
}
```

Subtyping

```
class StudentImpl implements Student {  
    Person p;  
    int regNum;  
    StudentImpl( String n, int rn ) { p = new PersonImpl( n ); regNum = rn; }  
    int getRegNum( ) { return regNum; }  
    void print( ) { p.print( ); System.out.println( regNum ); }  
}
```

Aggregation

Subtyping

Delegation

Specialization

Subtyping, Inheritance, and Subclassing

```
class Circle {  
    Point center;  
    float radius;  
  
    float getRadius( ) { ... }  
    float area( ) { ... }  
}
```

```
class Ellipse {  
    Point center;  
    float radiusA;  
    float radiusB;  
  
    float getRadiusA( ) { ... }  
    float getRadiusB( ) { ... }  
  
    float area( ) { ... }  
    void rotate( ) { ... }  
}
```

- How to define the subtype, inheritance, and subclass relationship between these two classes?

Circles and Ellipses: Subtyping

- A circle **is an** ellipse!

```
class Circle <: Ellipse {  
    Point center;  
    float radius;  
    float getRadius( ) { ... }  
    float area( ) { ... }  
}
```

```
class Ellipse {  
    Point center;  
    float radiusA;  
    float radiusB;  
    float getRadiusA( ) { ... }  
    float getRadiusB( ) { ... }  
    float area( ) { ... }  
    void rotate( ) { ... }  
}
```

- We need to **enrich Circle's interface**
 - Methods getRadiusA and getRadiusB return radius
 - Method rotate does nothing for Circle

Circles and Ellipses: Inheritance

- An ellipse has more features than a circle

```
class Circle {  
    Point center;  
    float radius;  
    float getRadius( ) { ... }  
    float area( ) { ... }  
}
```

```
class Ellipse inherits Circle {  
  
    float radiusB;  
    float getRadiusB( ) { ... }  
    float area( ) { ... }  
    void rotate( ) { ... }  
}
```

- Reuse center, radius, and getRadius
- Add extra fields and operations to Ellipse
- Override method area

Circles and Ellipses: Subclassing

- Subclassing includes subtyping
 - We must have an “is-a” relation

```
class Circle extends Ellipse {  
    // invariant radiusA == radiusB
```

```
    Circle( int r ) {  
        radiusA = r;  
        radiusB = r;  
    }  
}
```

Possibly override
rotate to improve
performance

```
class Ellipse {  
    Point center;  
    float radiusA;  
    float radiusB;  
  
    float area( ) {  
        return radiusA * radiusB * 3.14;  
    }  
  
    void rotate( ) {  
        // swap radiusA and radiusB  
    }  
}
```

Sets and Bounded Sets

```
class Set {  
    int size; // number of elements  
  
    ...  
  
    void add( Object o ) {  
        // add o to set  
    }  
  
    boolean contains( Object o ) { ... }  
}
```

```
class BoundedSet {  
    int size; // number of elements  
    int capacity; // maximum number  
  
    ...  
  
    void add( Object o ) {  
        // add o if there is still space  
    }  
  
    boolean contains( Object o ) { ... }  
}
```

- How to define the subtype, inheritance, and subclass relationship between these two classes?

Subtyping: BoundedSet <: Set

- BoundedSet specializes add method
- Precondition of add is strengthened
- Clients using Set might fail when using a BoundedSet
- BoundedSet is not a behavioral subtype of Set

```
class Set {  
    ...  
    // requires true  
    // ensures contains( o )  
    void add( Object o ) { ... }  
}
```

```
class BoundedSet extends Set {  
    int size, capacity;  
    // requires size < capacity  
    // ensures contains( o )  
    void add( Object o ) {  
        if ( size < capacity ) super.add( o );  
    }  
}
```

Subtyping: BoundedSet <: Set (cont'd)

```
class Set {  
  ...  
  // requires true  
  // ensures result => contains( o )  
  boolean add( Object o ) {  
    ...;  
    return true;  
  }  
}
```

Does not
specify result

```
class BoundedSet extends Set {  
  int size, capacity;  
  
  // requires true  
  // ensures result => contains( o )  
  // ensures result == old(size < capacity)  
  boolean add( Object o ) {  
    if ( capacity <= size ) return false;  
    return super.add( o );  
  }  
}
```

- Clients cannot rely on the properties of unbounded set (have to test for result of add)

Subtyping: Set <: BoundedSet

- Set must respect BoundedSet's invariant and history constraint
- Set.add cannot increase capacity when full
- Set is not a behavioral subtype of BoundedSet

```
class BoundedSet {  
    int size, capacity;  
  
    // invariant size <= capacity  
    // constraint old( capacity ) == capacity  
  
    // requires size < capacity  
    // ensures contains( o )  
    void add( Object o ) { ... }  
}
```

```
class Set extends BoundedSet {  
    // requires true  
    // ensures contains( o )  
    void add( Object o ) { ... }  
}
```

Subtyping: Set <: BoundedSet (cont'd)

- **Hack**: Assign a very high number to capacity in Set
- To maintain invariant, Set.add still requires precondition
- At least for static verification, Set behaves still like a bounded set

```
class BoundedSet {  
    int size, capacity;  
  
    // invariant size <= capacity  
    // constraint old( capacity ) == capacity  
  
    // requires size < capacity  
    // ensures contains( o )  
    void add( Object o ) { ... }  
}
```

```
class Set extends BoundedSet {  
    // requires size < capacity  
    // ensures contains( o )  
    void add( Object o ) { ... }  
}
```

Discussion

- The presented classes for Set and BoundedSet are not behavioral subtypes
 - Syntactic requirements are met
 - Semantic requirements are not met

- Large parts of the implementation are identical
 - This code should be reused

Solution 1: Aggregation

- BoundedSet **uses** Set
- Method calls are **delegated** to Set
- **No subtype relation**
 - No polymorphism
 - No behavioral subtyping requirements

```
class Set {  
    ...  
    void add( Object o ) { ... }  
    int  size( )         { ... }  
}
```

```
class BoundedSet {  
    Set rep;  
    int capacity;  
  
    void add( Object o ) {  
        if (rep.size( ) < capacity) rep.add( o );  
    }  
  
    int size( ) { return rep.size( ); }  
}
```

A Variant of the Problem

- Aggregation seems okay for Set and BoundedSet
- Similar examples require subtyping
- Polygons and Rectangles
 - Polygon: Unbounded set of vertices
 - Rectangle: Bounded set of (exactly four) vertices
 - A rectangle is a polygon!

```
class Polygon {  
    Vertex[ ] vertices;  
  
    ...  
    void addVertex( Vertex v ) { ... }  
}
```

```
class Rectangle  
    extends Polygon {  
    // vertices contains 4 vertices  
  
    ...  
    void addVertex( Vertex v ) {  
        // unsupported operation  
    }  
}
```

Not what
we want

Solution 2: Creating New Objects

```
class Polygon {  
    Vertex[ ] vertices;  
  
    ...  
    // requires true  
    // ensures result.hasVertex( v )  
    Polygon addVertex( Vertex v ) {  
        ... // add v to vertices  
        return this;  
    }  
}
```

```
class Rectangle extends Polygon {  
    // vertices contains 4 vertices  
  
    ...  
    // requires true  
    // ensures result.hasVertex( v )  
    Polygon addVertex( Vertex v ) {  
        return new Pentagon(  
            vertices[ 0 ], vertices[ 1 ],  
            vertices[ 2 ], vertices[ 3 ], v );  
    }  
}
```

```
void foo ( Polygon[ ] p, Vertex v ) {  
    for( int i=0; i < p.length; i++ ) { p[ i ].addVertex( v ).display( ); }  
}
```

Solution 2 for BoundedSet

```
class Set {  
    ...  
    // requires true  
    // ensures result.contains( o )  
    Set add( Object o ) {  
        ... // add o  
        return this;  
    }  
}
```

```
class BoundedSet extends Set {  
    int size, capacity;  
    // requires true  
    // ensures result.contains( o )  
    BoundedSet add( Object o ) {  
        if ( size < capacity )  
            return super.add( o );  
        else {  
            BoundedSet res =  
                new BoundedSet( 2*capacity );  
            res.addAll( this ); res.add( o );  
            return res;  
        }  
    }  
}
```

Discussion of Solution 2

- BoundedSet.add may return fresh object

- No problem for polymorphic client code

```
static Set union( Set a, Set b ) {  
    Set res = a;  
    for( Object e: b ) { res = res.add( e ); }  
    return res;  
}
```

- Most likely not what users of BoundedSet want

Solution 3: Weak Superclass Contract

- Behavioral subtyping is **relative to a contract**
- Introduce superclass with very **weak contract**
- Strengthen subtype contracts via postconditions

```
abstract class AbstractSet {  
    // invariant true  
    // constraint true  
    ...  
    // requires true  
    // ensures true  
    void add( Object o ) { // add o to set }  
}
```

```
class BoundedSet extends AbstractSet {  
    // requires true  
    // ensures old( size < capacity ) & contains( o )  
    void add( Object o )  
    { if ( size < capacity ) super.add( o ); }  
}
```

How to show that
call establishes
postcondition?

Discussion of Solution 3

- **Statically-bound methods** cannot be overridden
- **Behavioral subtyping** does not apply
- **Solution** requires extra method

```
abstract class AbstractSet {  
    ...  
    // requires true  
    // ensures contains( o )  
    final void doAdd( Object o ) { // add o to set }  
  
    // requires false  
    // ensures true  
    void add( Object o ) { doAdd( o ) }  
}
```

```
class BoundedSet extends AbstractSet {  
    // requires true  
    // ensures old( size < capacity ) => contains( o )  
    void add( Object o )  
    { if ( size < capacity ) doAdd( o ); }  
}
```

Discussion of Solution 3 (cont'd)

- Static contracts specify a given method implementation
- Statically-bound calls use combination of static and standard contract (analogous to effective pre and post)
- Dynamically-bound calls use standard contract

```
abstract class AbstractSet {  
    ...  
    // requires false  
    // ensures true  
    // static requires true  
    // static ensures contains( o )  
    void add( Object o ) { // add o to set }  
}
```

```
class BoundedSet extends AbstractSet {  
    // requires ...  
    // ensures ... // see previous slide  
    void add( Object o )  
    { if ( size < capacity ) super.add( o ); }  
}
```

Solution 4: Inheritance w/o Subtyping

- Some languages support **inheritance without subtyping**
 - C++:
private and protected inheritance
 - Eiffel: non-conforming inheritance

- No polymorphism**

```
void foo( BoundedSet b ) {  
    Set s = b; // compile-time error  
}
```

C++

```
class Set {  
public:  
    // requires true  
    // ensures contains( o )  
    void add( int o ) { ... }  
    bool contains( int o ) { ... }  
    ...  
}
```

C++

```
class BoundedSet : private Set {  
public:  
    void add( int o ) { ... }  
    Set::contains  
    ...  
}
```

Make method
public

Override
method

C++

Aggregation vs. Private Inheritance

- Both solutions allow code reuse without establishing a subtype relation
 - No subtype polymorphism
 - No behavioral subtyping requirements
- Aggregation causes more overhead
 - Two objects at run time
 - Boilerplate code for delegation
 - Access methods for protected fields
- Private inheritance may lead to unnecessary multiple inheritance

3. Inheritance

3.1 Inheritance and Subtyping

3.2 Dynamic Method Binding

3.3 Multiple Inheritance

3.4 Linearization

Method Binding

- Static binding:
At compile time, a method declaration is selected for each call based on the static type of the receiver expression
- Dynamic binding:
At run time, a method declaration is selected for each call based on the dynamic type of the receiver object

Static vs. Dynamic Method Binding

- Dynamic method binding enables specialization and subtype polymorphism
- However, there are important drawbacks
 - **Performance**: Overhead of method look-up at run-time
 - **Versioning**: Dynamic binding makes it harder to evolve code without breaking subclasses
- Defaults
 - Dynamic binding: Eiffel, Java, Scala, dynamically-typed languages
 - Static binding: C++, C#

Fragile Baseclass Scenario

- Software is not static
 - Maintenance
 - Bugfixing
 - Reengineering
- Subclasses can be affected by changes to superclasses
- How should we apply inheritance to make our code robust against revisions of superclasses?

Example 1: Selective Overriding

```
class Bag {  
    ...  
    int getSize( ) {  
        ... // count elements  
    }  
  
    void add( Object o )  
        { ... }  
  
    void addAll( Object[ ] arr ) {  
        for( int i=0; i < arr.length; i++ )  
            add( arr[ i ] );  
    }  
}
```

```
class CountingBag extends Bag {  
    int size;  
  
    int getSize( )  
        { return size; }  
    void add( Object o )  
        { super.add( o ); size++; }  
}
```

```
Object[ ] oa = ... // 5 elements  
CountingBag cb =  
    new CountingBag( );  
cb.addAll( oa );  
System.out.println( cb.getSize( ) );
```

Example 1: Selective Overriding (cont'd)

```
class Bag {  
    ...  
    int getSize( ) {  
        ... // count elements  
    }  
  
    void add( Object o )  
        { ... }  
  
    void addAll( Object[ ] arr ) {  
        // add elements of arr  
        // directly (not using add)  
    }  
}
```

```
class CountingBag extends Bag {  
    int size;  
  
    int getSize( )  
        { return size; }  
    void add( Object o )  
        { super.add( o ); size++; }  
}
```

```
Object[ ] oa = ... // 5 elements  
CountingBag cb =  
                new CountingBag( );  
cb.addAll( oa );  
System.out.println( cb.getSize( ) );
```

Example 1: Discussion

```
class Bag {
```

```
...
```

```
int getSize
```

```
... // cou
```

```
}
```

```
// requires true
```

```
// ensures  $\forall i. 0 \leq i < \text{arr.length}$ :
```

```
// contains( arr[ i ] )
```

```
void addAll( Object[ ] arr ) {
```

```
  for( int i=0; i < arr.length; i++ )
```

```
    add( arr[ i ] );
```

```
}
```

```
}
```

Subclass: Using inheritance, rely on interface documentation, not on implementation

Superclass: Do not change calls to dynamically-bound methods

```
class CountingBag extends Bag {
```

```
  int size;
```

```
  // invariant size==super.getSize( )
```

```
  ...
```

```
  void add( Object o )
```

```
  { super.add( o ); size++; }
```

```
  void addAll( Object[ ] arr ) {
```

```
    for( int i=0; i < arr.length; i++ )
```

```
      add( arr[ i ] );
```

```
  }
```

```
}
```

Subclass: Override all methods that could break invariants

Example 2: Unjustified Assumptions

```
class Math {
```

```
    float squareRt( float f ) {  
        return  $\sqrt{f}$ ;  
    }
```

```
    float fourthRt( float f ) {  
        return  $\sqrt{\sqrt{f}}$ ;  
    }  
}
```

```
class MyMath extends Math {
```

```
    float squareRt( float f ) {  
        return  $-\sqrt{f}$ ;  
    }  
}
```

```
MyMath m = new MyMath( );  
System.out.println  
    ( m.fourthRt( 16 ) );
```

Example 2: Unjustified Assumptions (c'd)

```
class Math {  
    // requires  $f \geq 0$   
    // ensures  $\text{result}^2 = f$   
    float squareRt( float f ) {  
        return  $\sqrt{f}$ ;  
    }  
    // requires  $f \geq 0$   
    // ensures  $\text{result}^4 = f$   
    float fourthRt( float f ) {  
        return squareRt( squareRt( f ) );  
    }  
}
```

Rely on interface documentation of dynamically-bound method, not on implementation

```
class MyMath extends Math {  
    // requires  $f \geq 0$   
    // ensures  $\text{result}^2 = f$   
    float squareRt( float f ) {  
        return  $-\sqrt{f}$ ;  
    }  
}
```

Superclass: Do not change calls to dynamically-bound methods

```
MyMath m = new MyMath( );  
System.out.println  
    ( m.fourthRt( 16 ) );
```

Example 3: Mutual Recursion

```
class C {  
    int x;  
  
    void inc1( ) {  
        x = x + 1;  
    }  
  
    void inc2( ) {  
        x = x + 1;  
    }  
}
```

```
class CS extends C {  
  
    void inc2( ) {  
        inc1( );  
    }  
}
```

```
CS cs = new CS( );  
cs.x = 5;  
cs.inc2( );  
System.out.println( cs.x );
```

Example 3: Mutual Recursion (cont'd)

```

class C {
    int x;
    // requires true
    // ensures x = old( x ) + 1
    void inc1( ) {
        inc2( );
    }
    // requires true
    // ensures x = old( x ) + 1
    void inc2( ) {
        x = x + 1;
    }
}

```

Superclass: Do not change calls to dynamically-bound methods

```

class CS extends C {
    // requires true
    // ensures x = old( x ) + 1
    void inc2( ) {
        inc1( );
    }
}

```

Subclass: Avoid specializing classes that are expected to be changed (often)

```

CS cs = new CS( );
cs.x = 5;
cs.inc2( );
System.out.println( cs.x );

```

Example 4: Additional Methods

```
class DiskMgr {  
  
    void cleanUp( ) {  
        ... // remove temporary files  
    }  
}
```

```
class MyMgr extends DiskMgr {  
    void delete( ) {  
        ... // erase whole hard disk  
    }  
}
```

```
MyMgr mm = new MyMgr( );  
...  
mm.cleanUp( );
```

Example 4: Additional Methods (cont'd)

```
class DiskMgr {  
    void delete( ) {  
        ... // remove temporary files  
    }  
  
    void cleanUp( ) {  
        delete( );  
    }  
}
```

Superclass: Do not change calls to dynamically-bound methods

```
class MyMgr extends DiskMgr {  
    void delete( )  
        ... // erase whole hard disk  
    }  
}
```

Subclass: Avoid specializing classes that are expected to be changed (often)

```
MyMgr mm = new MyMgr( );  
...  
mm.cleanUp( );
```

Example 4: Additional Methods (cont'd)

```
class DiskMgr {  
    virtual void delete( ) {  
        ... // remove temporary files  
    }  
  
    void cleanUp( ) {  
        delete( );  
    }  
}
```

C#

```
class MyMgr : DiskMgr {  
    new void delete( ) {  
        ... // erase whole hard disk  
    }  
}
```

C#

```
MyMgr mm = new MyMgr( );  
...  
mm.cleanUp( );
```

C#

- In C#, methods are bound statically by default
- Potential overrides must be declared as either **override** or **new**
 - Prevents accidental overriding

Example 5: Additional Methods

```
class Super {
```

```
}
```

Java

```
class Sub extends Super {
```

```
    void foo( Object o ) { ... }
```

```
    void bar( double i ) { ... }
```

```
}
```

Java

```
Sub s = new Sub( );
```

```
s.foo( "Java" );
```

```
s.bar( 5 );
```

Java

Example 5: Additional Methods (cont'd)

```
class Super {  
    void foo( String o ) { ... }  
    void bar( int i ) { ... }  
}
```

Java

```
class Sub extends Super {  
    void foo( Object o ) { ... }  
    void bar( double i ) { ... }  
}
```

Java

```
Sub s = new Sub( );  
s.foo( "Java" );  
s.bar( 5 );
```

Java

- Overloading resolution in Java chooses **most specific** method declaration
- Adding methods to a superclass may affect clients of subclasses
 - Even without overriding
 - When the client is re-compiled

Example 5: Additional Methods (cont'd)

```
class Super {  
    void foo( string o ) { ... }  
    void bar( int i ) { ... }  
}
```

C#

```
class Sub : Super {  
    void foo( object o ) { ... }  
    void bar( double i ) { ... }  
}
```

C#

```
Sub s = new Sub( );  
s.foo( "C#" );  
s.bar( 5 );
```

C#

- Overloading resolution in C# chooses **most specific** method declaration **in the class of the receiver**
 - Then superclass, etc.
- Adding methods to a superclass does not affect overloading resolution

Summary: Rules for Proper Subclassing

- Use subclassing only if there is an “is-a” relation
 - Syntactic and **behavioral** subtypes
- Do not rely on implementation details
 - Use **precise documentation** (**contracts** where possible)
- When evolving superclasses, **do not mess around with dynamically-bound methods**
 - Do not add or remove calls, or change order of calls
- Do not specialize superclasses that are expected to change often

Binary Methods

- Binary methods take receiver and one explicit argument
- Often behavior should be specialized depending on the dynamic types of both arguments
- Recall that covariant parameter types are not statically type-safe

```
class Object {  
    boolean equals( Object o ) {  
        return this == o;  
    }  
}
```

```
class Cell {  
    int val;  
    boolean equals( Cell o ) {  
        return this.val == o.val;  
    }  
}
```

Binary Methods: Example

- **Dynamic binding for specialization based on dynamic type of receiver**
- How to specialize based on dynamic type of explicit argument?

```
class Shape {  
    Shape intersect( Shape s ) {  
        // general code for all shapes  
    }  
}
```

```
class Rectangle extends Shape {  
    Shape intersect( Rectangle r ) {  
        // efficient code for two rectangles  
    }  
}
```

Solution 1: Explicit Type Tests

- Type test and conditional for specialization based on dynamic type of explicit argument
- Problems
 - Tedious to write
 - Code is not extensible
 - Requires type cast

```
class Rectangle extends Shape {  
    Shape intersect( Shape s ) {  
        if( s instanceof Rectangle ) {  
            Rectangle r = ( Rectangle ) s;  
            // efficient code for two rectangles  
        } else {  
            return super.intersect( s );  
        }  
    }  
}
```

Solution 2: Double Invocation

```
class Shape {  
    Shape intersect( Shape s )  
    { return s.intersectShape( this ); }  
  
    Shape intersectShape( Shape s )  
    { // general code for all shapes }  
  
    Shape intersectRectangle( Rectangle r )  
    { return intersectShape( r ); }  
}
```

- Additional dynamically-bound call for specialization based on dynamic type of explicit argument

```
class Rectangle extends Shape {  
    Shape intersect( Shape s )  
    { return s.intersectRectangle( this ); }  
  
    Shape intersectRectangle( Rectangle r )  
    { // efficient code for two rectangles }  
}
```

Solution 2: Double Invocation (cont'd)

Corresponds to
Node and Visitor

Corresponds to
Node.accept

- Double invocation is also called
Visitor Pattern

```
class Shape {  
    Shape intersect( Shape s )  
    { return s.intersectShape( this ); }  
  
    Shape intersectShape( Shape s )  
    { // general code for all shapes }  
  
    Shape intersectRectangle( Rectangle r )  
    { return intersectShape( r ); }  
}
```

Corresponds to
Visitor.visitX

- Problems
 - Even more tedious to write
 - Requires modification of superclass
(not possible for equals method)

Solution 3: Overloading plus Dynamic

```
class Shape {  
    Shape intersect( Shape s )  
    { // general code for all shapes }  
}
```

C#

```
class Rectangle extends Shape {  
    Rectangle intersect( Rectangle r )  
    { // efficient code for two rectangles }  
}
```

Overloads
Shape's method

C#

```
static Shape intersect( Shape s1, Shape s2 ) {  
    return ( s1 as dynamic ).intersect( s2 as dynamic );  
}
```

Dynamic resolution
depends on dynamic
types of both arguments

the receiver has
, this call
solved to
hod

Solution 3: Overloading plus Dynamic (c'd)

```
class Shape {  
    Shape intersect( Shape s )  
    { // general code for all shapes }  
}
```

C#

```
class Rectangle : Shape {  
    Rectangle intersect( Rectangle r )  
    { // efficient code for two rectangles }  
}
```

C#

```
static Shape intersect( Shape s1, Shape s2 ) {  
    return  
    ( s1 as dynamic ).intersect( s2 as dynamic );  
}
```

C#

- Concise
- No change to superclass required
- Problems
 - Not entirely type safe
 - Overhead for run-time checks

Solution 4: Multiple Dispatch

- Some research languages allow method calls to be bound based on the **dynamic type of several arguments**
- Examples: CLU, Cecil, Fortress, MultiJava

```
class Shape {  
    Shape intersect( Shape s ) {  
        // general code for all shapes  
    }  
}
```

```
class Rectangle extends Shape {  
    Shape intersect( Shape@Rectangle r ) {  
        // efficient code for two rectangles  
    }  
}
```

Static type
of r

Dispatch
on r

Solution 4: Multiple Dispatch (cont'd)

- Multiple dispatch is statically type-safe

```
Shape client( Shape s1, Shape s2) {  
    return s1.intersect( s2 );  
}
```

Calls `Rectangle.intersect`
only if `s1` and `s2` are of
type `Rectangle`

- Problems

- Performance overhead of method look-up at run time
- Extra requirements are needed to ensure there is a “unique best method” for every call

Binary Methods: Summary

- The behavior of binary methods often depends on the dynamic types of both arguments
- Type tests
 - One single-dispatch call and one case distinction
- Double invocation (Visitor Pattern)
 - Two single-dispatch calls
- Overloading plus dynamic
 - Dynamic resolution based on dynamic argument types
- Multiple dispatch
 - One multiple-dispatch call

3. Inheritance

3.1 Inheritance and Subtyping

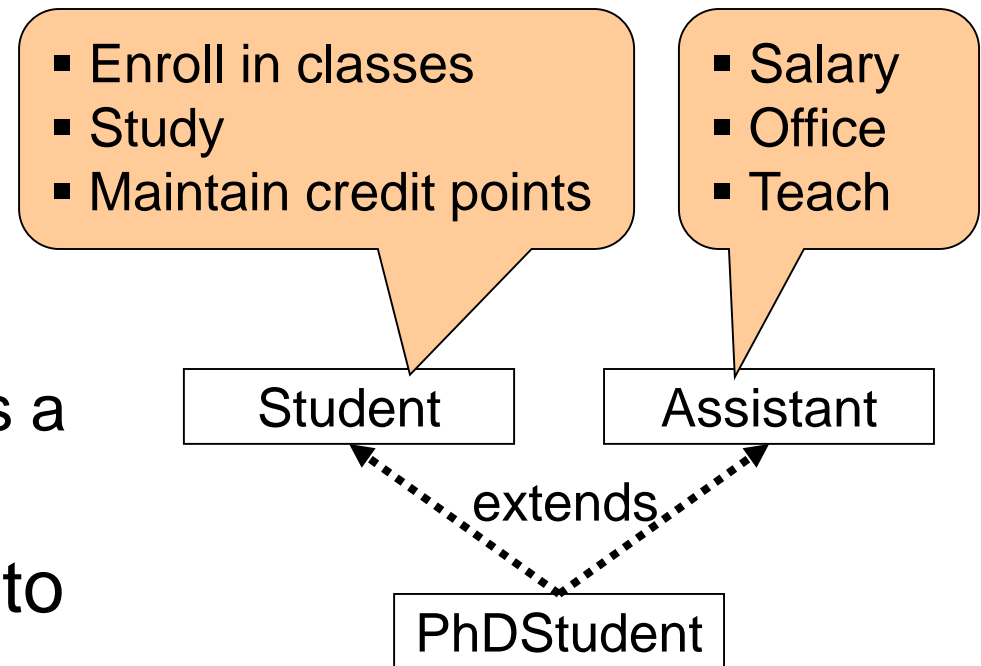

3.2 Dynamic Method Binding

3.3 Multiple Inheritance

3.4 Linearization

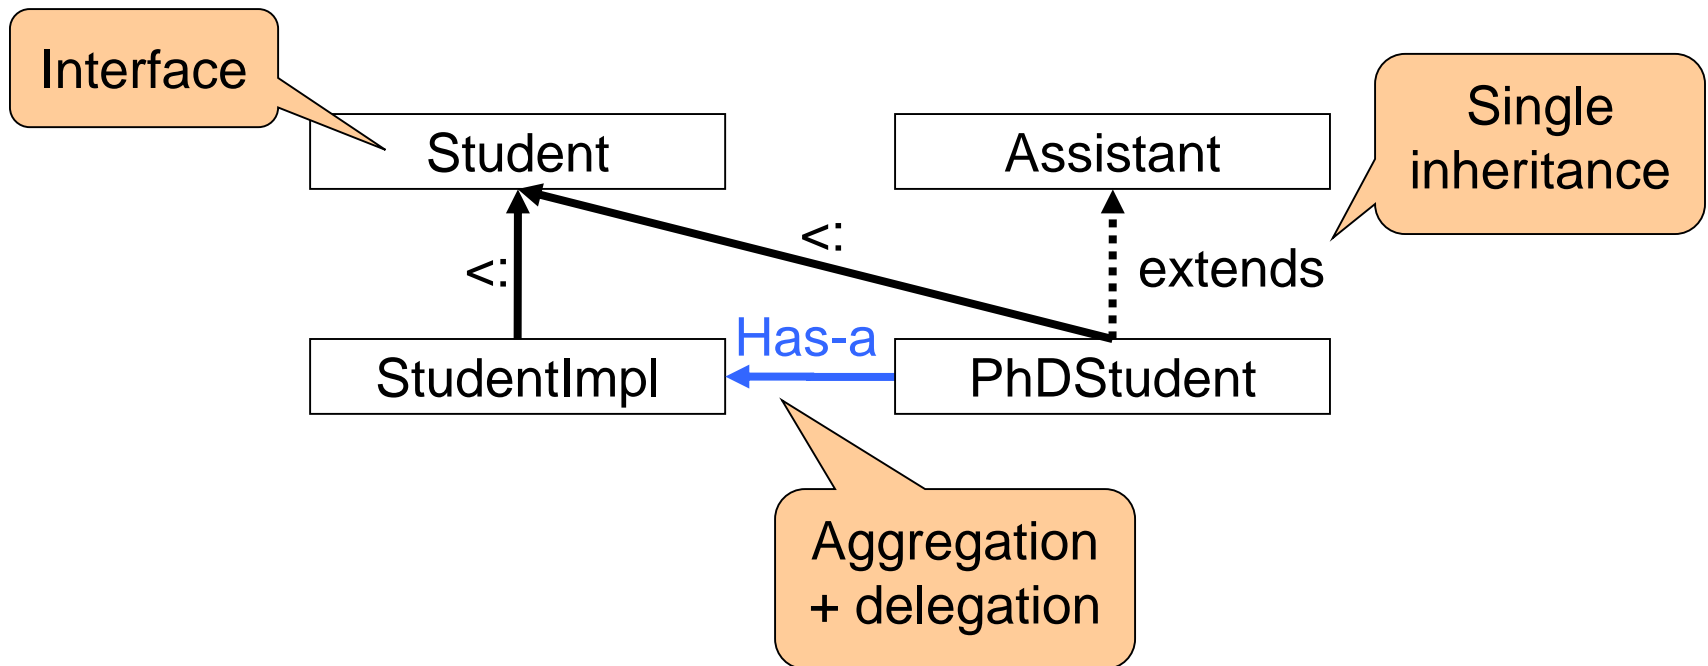

Motivation

- All object-oriented languages support multiple subtyping
 - One type can have several supertypes
 - Subtype relation forms a DAG
- Often it is also useful to **reuse code from several superclasses** via multiple inheritance

Simulating Multiple Inheritance

- Java and C# support only single inheritance
- Multiple inheritance is simulated via delegation
 - Not elegant

Problems of Multiple Inheritance

- Ambiguities

- Superclasses may contain fields and methods with identical names and signatures
- Which version should be available in the subclass?

- Repeated inheritance (diamonds)

- A class may inherit from a superclass more than once
- How many copies of the superclass members are there?
- How are the superclass fields initialized?

Ambiguities: Example

```
class Student {  
    public:  
        Professor* mentor;  
        virtual int workLoad( ) { ... }  
        ... };
```

C++

```
class Assistant {  
    public:  
        Professor* mentor;  
        virtual int workLoad( ) { ... }  
        ... };
```

C++

```
class PhDStudent :  
    public Student, public Assistant {  
};
```

C++

Which method
should be called?

```
void client( PhDStudent p ) {  
    int w = p.workLoad( );  
    p.mentor = NULL;  
}
```

Which field
should be
accessed?

Ambiguity Resolution: Explicit Selection

```
class Student {  
    public:  
        Professor* mentor;  
        virtual int workLoad( ) { ... }  
        ... };
```

C++

```
class Assistant {  
    public:  
        Professor* mentor;  
        virtual int workLoad( ) { ... }  
        ... };
```

C++

```
class PhDStudent :  
    public Student, public Assistant {  
};
```

C++

```
void client( PhDStudent p ) {  
    int w = p.Assistant::workLoad( );  
    p.Student::mentor = NULL;  
}
```

- Subclass has two members with identical names
- Ambiguity is resolved by client
- Clients need to know implementation details

Ambiguity Resolution: Merging Methods

```
class PhDStudent  
    public Student, public Assistant {  
public:  
    virtual int workload( ) {  
        return Student::workLoad( ) +  
            Assistant::workLoad( );  
    }  
};
```

Overrides both
inherited methods

Correspond to
super-calls in Java

```
void client( PhDStudent p ) {  
    int w = p.workLoad( );  
}
```

- Related inherited methods can be merged into one overriding method
- Usual rules for overriding apply
 - Type rules
 - Behavioral subtyping

Merging Unrelated Methods

```
class Student {  
public:  
    virtual bool test( ) { // take exam }  
    ... };
```

C++

```
class Assistant {  
public:  
    virtual bool test( ) { // unit test }  
    ... };
```

Clients can call
Assistant::test

```
class PhDStudent :  
    public Student, public Assistant {  
public:  
    virtual bool test( )  
    { return Student::test( ); }  
};
```

C++

Violates
behavioral
subtyping

- Unrelated methods cannot be merged in a meaningful way
 - Even if signatures match
- Subclass should provide both methods, but with different names

Ambiguity Resolution: Renaming

```
class Student
feature
  test: BOOLEAN do ... end
end
```

Eiffel

```
class Assistant
feature
  test: BOOLEAN do ... end
end
```

Eiffel

```
class PhDStudent inherit
  Student
  rename test as takeExam
  redefine takeExam end
  Assistant
end
```

Eiffel

- Inherited methods can be renamed
- Dynamic binding takes renaming into account

```
client( s: Student ): BOOLEAN
do
  Result := s.test( )
end
```

For PhDStudent
bound to takeExam

- C++/CLI provides similar features

Repeated Inheritance: Example

```
class Person {  
    Address address;  
    ...  
};
```

C++

```
class Student : public Person {  
    ...  
};
```

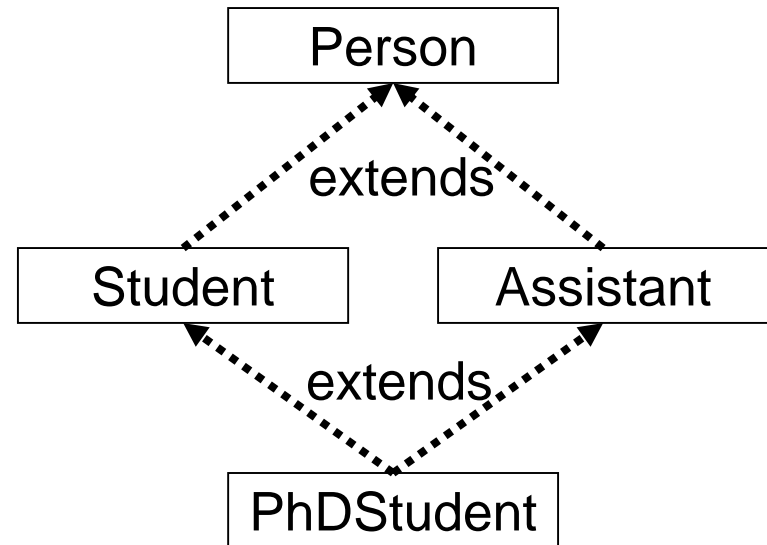

C++

```
class Assistant : public Person {  
    ...  
};
```

C++

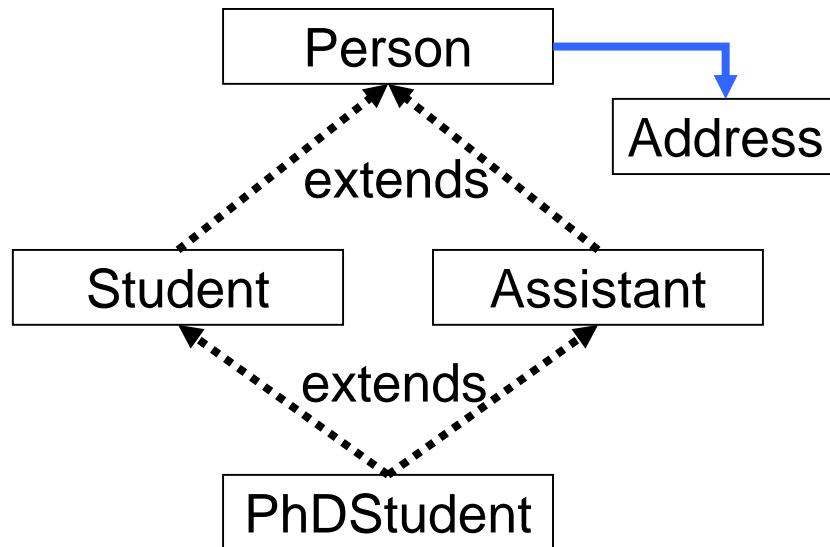

```
class PhDStudent :  
    public Student, public Assistant {  
};
```

C++

- How many address fields should PhDStudent have?
- How are they initialized?

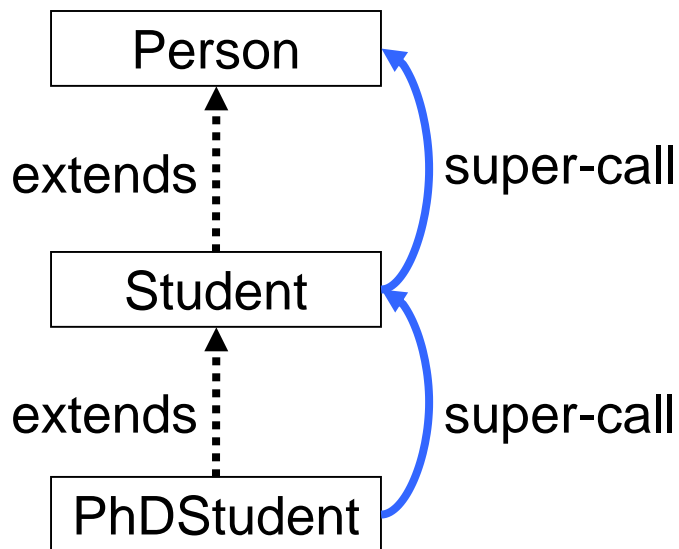

How Many Copies of Superclass Fields?

- Eiffel: default
- C++: virtual inheritance
- Eiffel: via renaming
- C++: non-virtual inheritance

Inheritance and Object Initialization

- **Superclass fields** are initialized **before subclass fields**
 - Helps preventing use of uninitialized fields, e.g., in inherited methods
- Order is typically implemented via mandatory call of superclass constructor at the beginning of each constructor

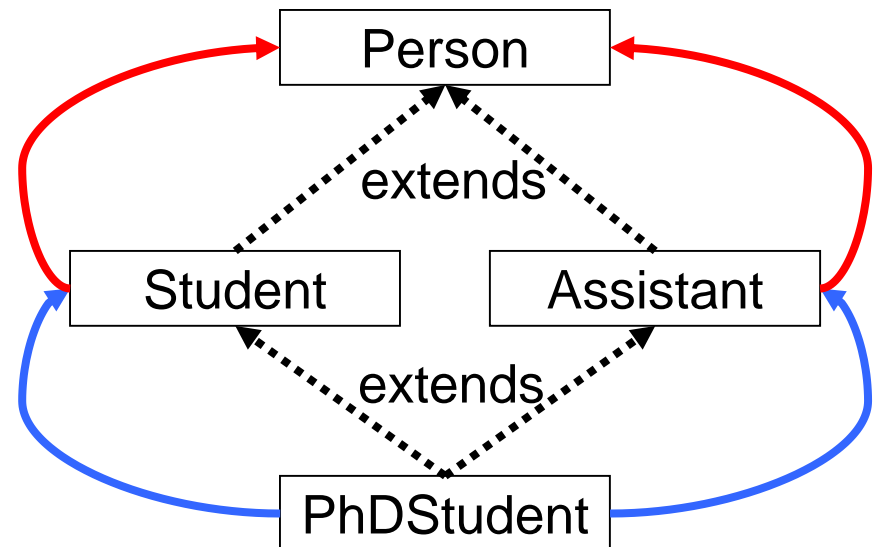

Initialization and Non-Virtual Inheritance

- With non-virtual inheritance, there are **two copies** of the superclass fields
- Superclass **constructor is called twice** to initialize both copies
 - Here, create two file handles for two files

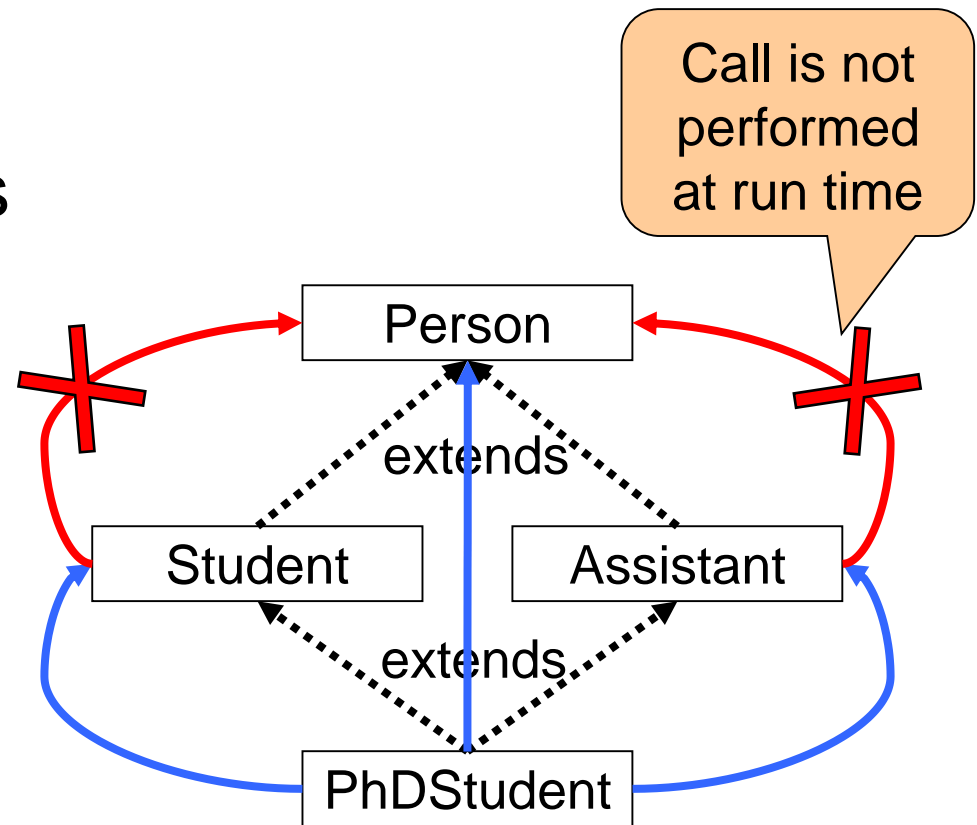

Initialization and Virtual Inheritance

- With virtual inheritance, there is **only one copy** of the superclass fields
- Who gets to call the superclass constructor?

Initialization: C++ Solution

- **Constructor** of repeated superclass is **called only once**
- **Smallest subclass** needs to call the constructor of the virtual superclass directly

C++ Solution: Example

```
class Person {  
    Address* address;  
    int workdays;  
public:  
    Person( Address* a, int w ) {  
        address = a;  
        workdays = w;  
    };  
};
```

```
class Student : virtual public Person {  
public:  
    Student( Address* a ) : Person( a, 5 ) { };  
};
```

```
class Assistant: virtual public Person {  
public:  
    Assistant( Address* a ) : Person( a, 6 ) { };  
};
```

```
class PhDStudent : public Student, public Assistant {  
public:  
    PhDStudent( Address* a ) : Person( a, 7 ), Student( a ), Assistant( a ) { };  
};
```

C++ Solution: Discussion

```
class Student : virtual public Person {  
  public:  
    Student( Address* a ) : Person( a, 5 ) {  
      assert( workdays == 5 );  
    };  
};
```

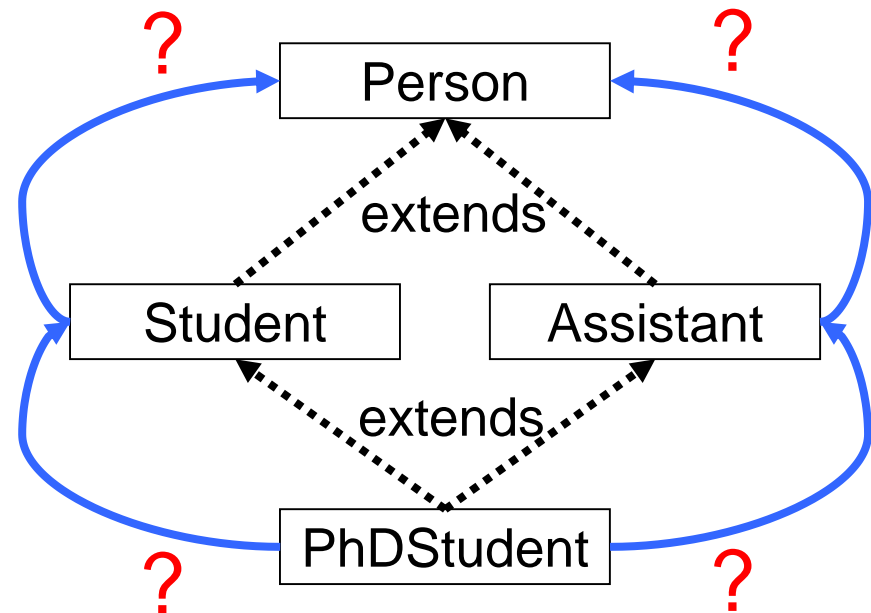

Might fail

- Non-virtual inheritance is the default
 - Virtual inheritance leads to run-time overhead
 - **Programmers need foresight!**
- Constructors **cannot rely on the virtual superclass constructors** they call
 - For instance, to establish invariants

Initialization: Eiffel Solution

- Eiffel **does not force** constructors to call superclass constructors
- Programmer has **full control** over calls to superclass constructors

Eiffel Solution: Discussion

No call of superclass constructor

- Subclasses have to initialize inherited fields
 - Code duplication
- Subclasses need to understand superclass implementation

Policy: Always call superclass constructor

- Constructors of repeated superclasses get called twice
- What if these super-calls have different arguments?
- Problematic if constructor has side-effects

Renaming Revisited

```
class Person  
feature  
  foo: BOOLEAN do ... end  
end
```

Eiffel

```
class Student inherit  
  Person rename foo as bar end  
end
```

Eiffel

```
class Assistant inherit Person  
end
```

Eiffel

```
class PhDStudent inherit  
  Student redefine bar select bar end  
  Assistant  
... end
```

Eiffel

```
client( p: Person ): BOOLEAN  
do  
  Result := p.foo( )  
end
```

For PhDStudent,
call foo or bar?

Multiple Inheritance

Pros

- Increases expressiveness
- Avoids overhead of delegation pattern

Cons

- Ambiguity resolution
 - Explicit selection
 - Merging
 - Renaming
- Repeated inheritance
 - Complex semantics
 - Initialization
 - Renaming
- Complicated!

3. Inheritance

3.1 Inheritance and Subtyping

3.2 Dynamic Method Binding

3.3 Multiple Inheritance

3.4 Linearization

Mixins and Traits

- Mixins and traits provide a form of reuse
 - Methods and state that can be **mixed into various classes**
 - Example: Functionality to persist an object
- Main applications
 - Making thin interfaces thick
 - Stackable specializations
- Languages that support mixins or traits: Python, Ruby, Scala, Squeak Smalltalk
 - We will focus on Scala's version of traits

Scala: Trait Example

```
class Cell {  
  var value: Int = 0  
  
  def put( v: Int ) = { value = v }  
  def get: Int = value  
}
```

Scala

```
trait Backup extends Cell {  
  var backup: Int = 0;  
  
  override def put( v: Int ) = {  
    backup = value  
    super.put( v )  
  }  
  def undo = { super.put( backup ) }  
}
```

Scala

```
object Main1 {  
  def main( args: Array[ String ] ) {  
    val a = new Cell with Backup  
    a.put( 5 )  
    a.put( 3 )  
    a.undo  
    println( a.get )  
  }  
}
```

Scala

Scala: Declaration of Traits

Traits may have fields

Traits may override superclass methods

Traits may declare methods

```
trait Backup extends Cell {  
  var backup = 0;  
  
  override def put( v: Int ) = {  
    backup = value  
    super.put( v )  
  }  
  
  def undo = { super.put( backup ) }  
}
```

Scala

Traits extend exactly one superclass (and possibly other traits)

Scala: Mixing-in Traits

```
class FancyCell extends Cell with Backup {  
  ...  
}
```

Traits can be mixed-in when classes are declared

```
def main( args: Array[String] ) {  
  val a = new Cell with Backup  
  ...  
}
```

Traits can be mixed-in when classes are instantiated

- Class must be a subclass of its traits' superclasses
 - To avoid multiple inheritance among classes

Traits and Types

- Each trait defines a type
 - Like classes and interfaces
 - Trait types are abstract
- Extending or mixing-in a trait introduces a subtype relation

```
trait Backup extends Cell {  
  ...  
}
```

Scala

```
class FancyCell  
  extends Cell with Backup {  
  ...  
}
```

Scala

```
val a: Backup = new FancyCell  
val b: Cell = a
```

Scala

Example: Thin and Thick Interfaces

- Traits can extend thin interfaces by additional operations
- Allows very specific types with little syntactic overhead
 - See structural subtyping

```
class ThinCollection {  
  def add( s: String ) = { ... }  
  def contains( s: String ): Boolean = { ... }  
}
```

```
trait AddAll extends ThinCollection {  
  def addAll( a: Array[String] ) = {  
    val it = a.iterator  
    while( it.hasNext ) { add( it.next ) }  
  }  
}
```

```
def client ( p: ThinCollection with AddAll, a: Array[String] ) = { p.addAll( a ) }
```

Ambiguity Resolution

```
trait Student {  
  var mentor: Professor  
  def workLoad: Int = 5  
}
```

```
trait Assistant {  
  var mentor: Professor  
  def workLoad: Int = 6  
}
```

```
class PhDStudent  
  extends AnyRef  
  with Student  
  with Assistant { }
```

- Ambiguity is resolved by **merging**
 - No scope-operator like in C++
 - No renaming like in Eiffel

Ambiguity Resolution (cont'd)

```
trait Student {  
  def workLoad: Int = 5  
}
```

```
trait Assistant {  
  def workLoad: Int = 6  
}
```

- Subclass overrides both mixed-in methods
- Does not work for mutable fields

```
class PhDStudent extends AnyRef with Student with Assistant {  
  override def workLoad: Int = {  
    super[ Student ].workLoad +  
    super[ Assistant ].workLoad  
  }  
}
```

Ambiguity Resolution and Diamonds

```
class Person {  
  def workLoad: Int = 0  
}
```

```
trait Student extends Person {  
  override def workLoad: Int = 5  
}
```

```
trait Assistant extends Person {  
  override def workLoad: Int = 6  
}
```

```
class PhDStudent  
  extends Person  
  with Student  
  with Assistant { }
```

- If two inherited methods override a common superclass method, merging is **not** required
- What is the behavior of `workLoad` in `PhDStudent`?

Linearization

- The key concept to understanding the semantics of Scala traits: bring **types in a linear order**
 - Define overriding and super-calls according to this order
- For a class or template
C extends C' with C₁ ... with C_n
the linearization L(C) is
$$C, L(C_n) \bullet \dots \bullet L(C_1) \bullet L(C')$$
- Do not include types more than once
$$\varepsilon \bullet B = B$$
$$(a, A) \bullet B = \begin{cases} a, (A \bullet B) & \text{if } a \notin B \\ A \bullet B & \text{otherwise} \end{cases}$$

Linearization Example

```
class Person
```

```
trait Student extends Person
```

```
trait Assistant extends Person
```

```
class PhDStudent  
    extends Person  
    with Student  
    with Assistant
```

$L(\text{Person}) = \text{Person}$

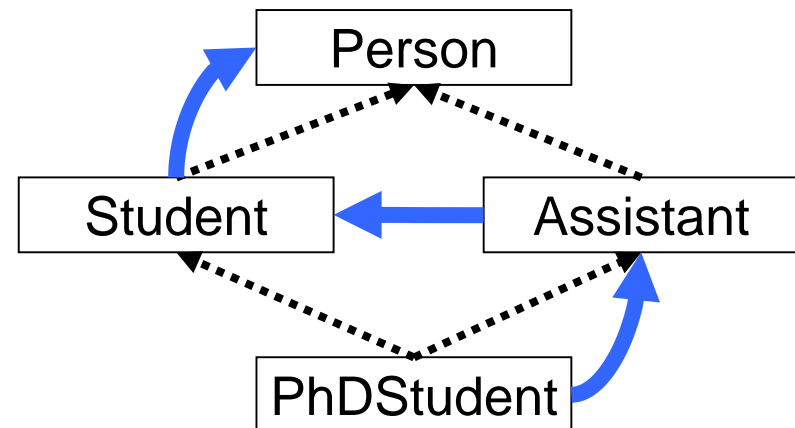

$L(\text{Student}) = \text{Student}, \text{Person}$

$L(\text{Assistant}) = \text{Assistant}, \text{Person}$

$L(\text{PhDStudent}) = \text{PhDStudent}, L(\text{Assistant}) \bullet L(\text{Student}) \bullet L(\text{Person})$

For a class or template

C extends C' with C₁ ... with C_n
the linearization $L(C)$ is
 $C, L(C_n) \bullet \dots \bullet L(C_1) \bullet L(C')$

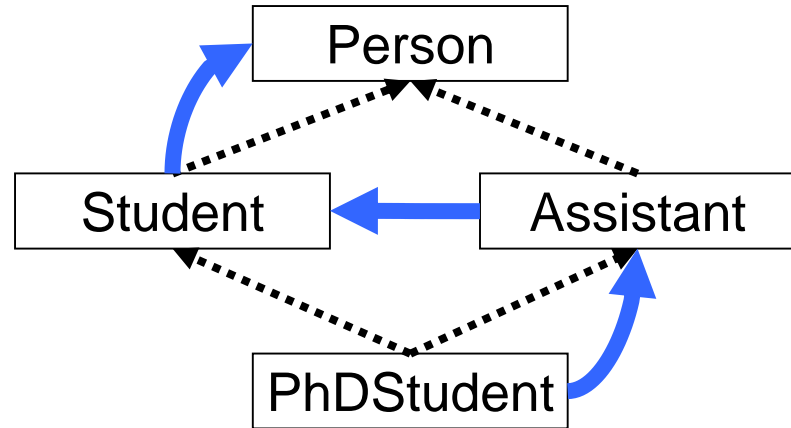

Overriding and Super-Calls

```
class Person {  
  def workLoad: Int = 0  
}
```

```
trait Student extends Person {  
  override def workLoad: Int = 5  
}
```

```
trait Assistant extends Person {  
  override def workLoad: Int = 6  
}
```

```
class PhDStudent  
  extends Person  
  with Student  
  with Assistant { }
```

- PhDStudent's workLoad method is inherited from Assistant
 - Assistant's workLoad overrides Student's
 - Student's workLoad overrides Person's

Overriding and Super-Calls (cont'd)

```
trait Student  
{ def workLoad: Int = 5 }
```

```
trait Assistant  
{ def workLoad: Int = 6 }
```

```
class PhDStudent extends AnyRef  
  with Student with Assistant {  
  def override workLoad: Int =  
    super.workLoad  
}
```

- PhDStudent's workLoad overrides methods from Assistant and Student
 - Super-call refers to predecessor in the linear order, Assistant
- Now Assistant's and Student's workLoad **do not override each other**
 - No super-calls allowed

Repeated Inheritance

```
class A {  
  var f = 0  
  def foo = println( "A::foo" )  
}
```

```
trait B extends A {  
  override def foo = println( "B::foo" )  
}
```

```
trait C extends A {  
  override def foo = println( "C::foo" )  
}
```

```
class D extends A with B with C {  
}
```

- Subclass inherits only **one copy** of repeated superclass
 - Like Eiffel and virtual inheritance in C++

Initialization Order

```
class A {  
  println( "Constructing A" )  
}
```

```
trait B extends A {  
  println( "Constructing B" )  
}
```

```
trait C extends A {  
  println( "Constructing C" )  
}
```

```
class D extends A with B with C {  
  println( "Constructing D" )  
}
```

- Classes and traits are initialized in the reverse linear order

Initialization of Repeated Superclasses

- Each constructor is called **exactly once**
 - Good if constructor has side-effects
- Arguments to superclass constructors are supplied **by immediately preceding class** in the linearization order

```
class A( x: Int ) {  
    println( "Constructing A" + x )  
}
```

```
trait B extends A { ... }
```

```
trait C extends A { ... }
```

```
class D extends A( 5 )  
    with B with C { ... }
```

Overriding and Super-Calls Revisited

```
class A {  
  def foo = println( "A::foo" )  
}
```

```
trait B extends A {  
  override def foo =  
    { println( "B::foo" ); super.foo }  
}
```

```
trait C extends A {  
  override def foo =  
    { println( "C::foo" ); super.foo }  
}
```

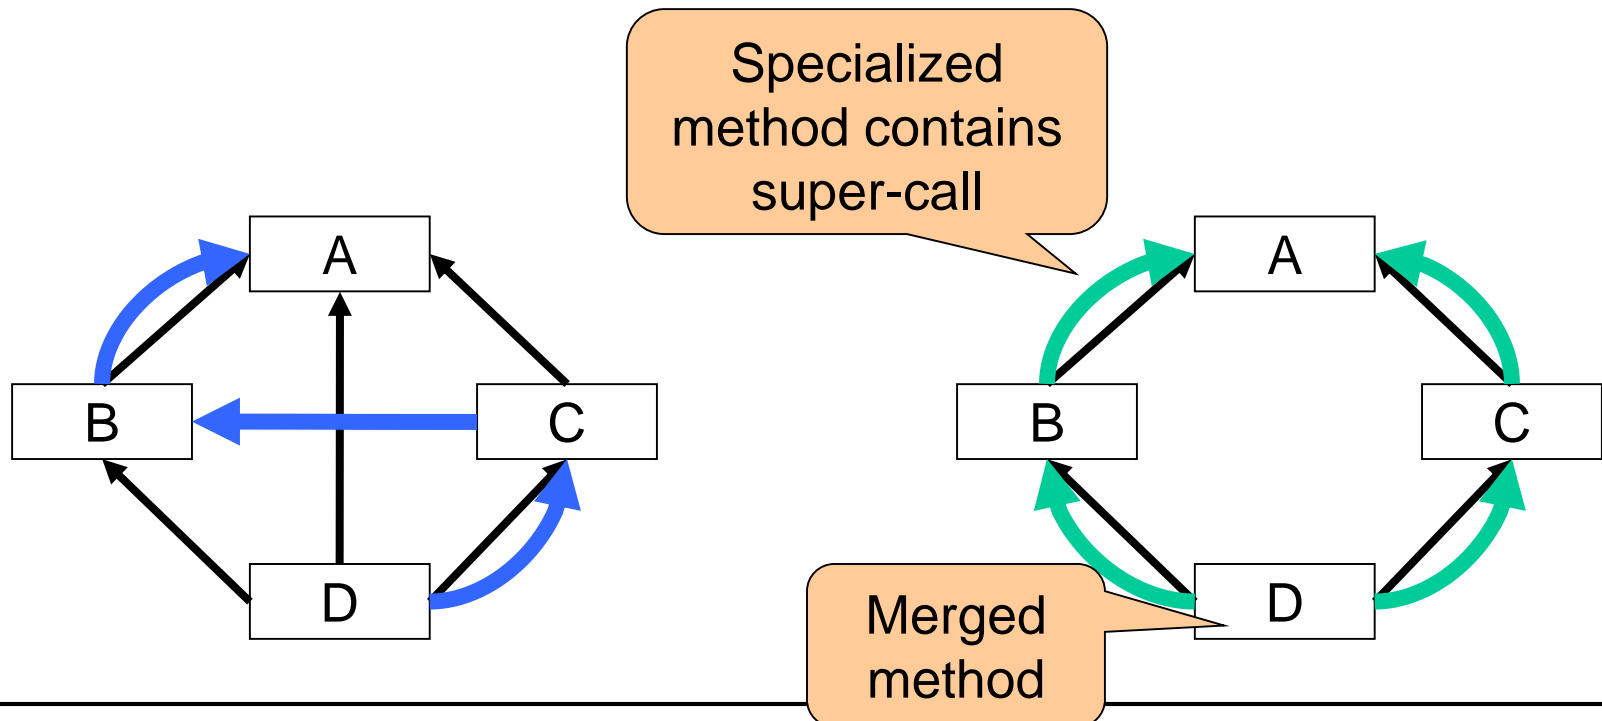

```
class D extends A with B with C { }
```

```
def client ( d: D ) = { d.foo }
```

Stackable Specializations

- With traits, specializations can be combined in flexible ways
- With multiple inheritance, methods of repeated superclasses are called twice

Stackable Specializations: Example

```
class Queue {  
  ...  
  def put( x: Data ) { ... }  
}
```

```
trait Timer extends Queue {  
  override def put( x: Data )  
  { x.SetTime( ... ); super.put( x ) }  
}
```

```
trait Filter extends Queue {  
  override def put( x: Data )  
  { if( x.Time > ... ) super.put( x ) }  
}
```

```
class SensorData extends Queue  
  with Filter with Timer { }
```

Traits and Behavioral Subtyping

```
trait B extends A {  
  override def foo =  
    { println( "B::foo" ); super.foo }  
}
```

```
trait C extends A {  
  override def foo =  
    { println( "C::foo" ); super.foo }  
}
```

```
class D extends A with B with C { }
```

```
class D extends A with C with B { }
```

- Overriding of trait methods depends on order of mixing
- Behavioral subtyping could be checked only when traits are mixed in

Reasoning About Traits

- Traits are very dynamic, which complicates static reasoning
- Traits do not know **how their superclasses get initialized**
- Traits do not know **which methods they override**
- Traits do not know **where super-calls are bound to**

```
trait B extends A {  
  override def foo =  
    { println( "B::foo" ); super.foo }  
}
```

```
trait C extends A {  
  override def foo =  
    { println( "C::foo" ); super.foo }  
}
```

Linearization: Summary

- Linearization partly solves problems of multiple inheritance
 - Solves some issues with ambiguities and initialization
- Other problems remain
 - Resolving ambiguities between unrelated methods
- And new problems arise
 - Behavioral subtyping cannot be checked modularly
 - What to assume about superclass initialization and super-calls
- Linearization poses several research challenges
