

# Example Questions

Security of Wireless Networks

# Question 1 (Key Establishment)

Question 1.1: What are the basic requirements of the uncoordinated frequency hopping (UHF)? (3 Marks)

Answer 1.1:

- a)  $P_a > P_t$  (Received power of the legitimate transmission ( $P_a$ ) is enough to decode the message)
- b) Transmitter (A) send on the same channel as the receiver (B) is listening
- c) Each node holds a public/private key pair and capable of performing public key operations.

# Question 1 (Key Establishment)

Question 1.2: What the main components of the UFH message transfer process? (2 Marks)

Answer 1.2:

- a) Fragmentation
- b) Transmission
- c) Reassembly

# Question 2 (GPS)

Question 2.1: Explain signal-synthesis and selective-delay attack.

Answer 2.1:

# GPS spoofing attacks

# Question 2 (GPS)

Question 2.2: Explain the hidden markers approach to prevent signal-synthesis and selective-delay attack. What are the assumptions on the time synchronization of the receiver's clock?

Answer 2.2:

# Proposal for a Secure GPS (Kuhn)

Devices hold satellite public keys

At time  $t$ , a satellite uses a secret code to spread the navigation signal

- The receiver uses a broadband receiver to receive the whole signal band (receiver does not know the desreading code yet)
- At time  $t+dt$ , the satellite discloses its secret code, signed with its private key
- The receiver gets the code, verifies the signatures and de-spreads the signals.

*Prevents the generation of fake signals and their individual shifts.*

# Question 2 (GPS)

Question 2.3: There are two GPS receivers, at coordinates  $(0,0)$  and  $(0,10)$ . A spoofer, located at  $(5,0)$ , transmits signals that make receiver 1 believe it's at  $(10,0)$ . Assume receiver 2 receives the same signals: Where is it being spoofed?

Answer 2.3:  $(10,0)$

# Question 3 (Distance Bounding)

Question 3.1: What are the properties of Verifiable Multilateration?

Answer 3.1:

# Verifiable Multilateration

## Properties:

1. *P cannot successfully claim to be at  $P' \neq P$ , where  $P'$  is within the triangle*
2. *M cannot convince Vs and P that P is at  $P' \neq P$  where  $P'$  is within the triangle*
3. *P or M can spoof a location from P to  $P'$  where  $P'$  is outside the triangle*

# Question 3 (Distance Bounding)

Question 3.2: What are the security vulnerabilities in the following distance bounding protocol (6 Marks)

Answer 3.2:

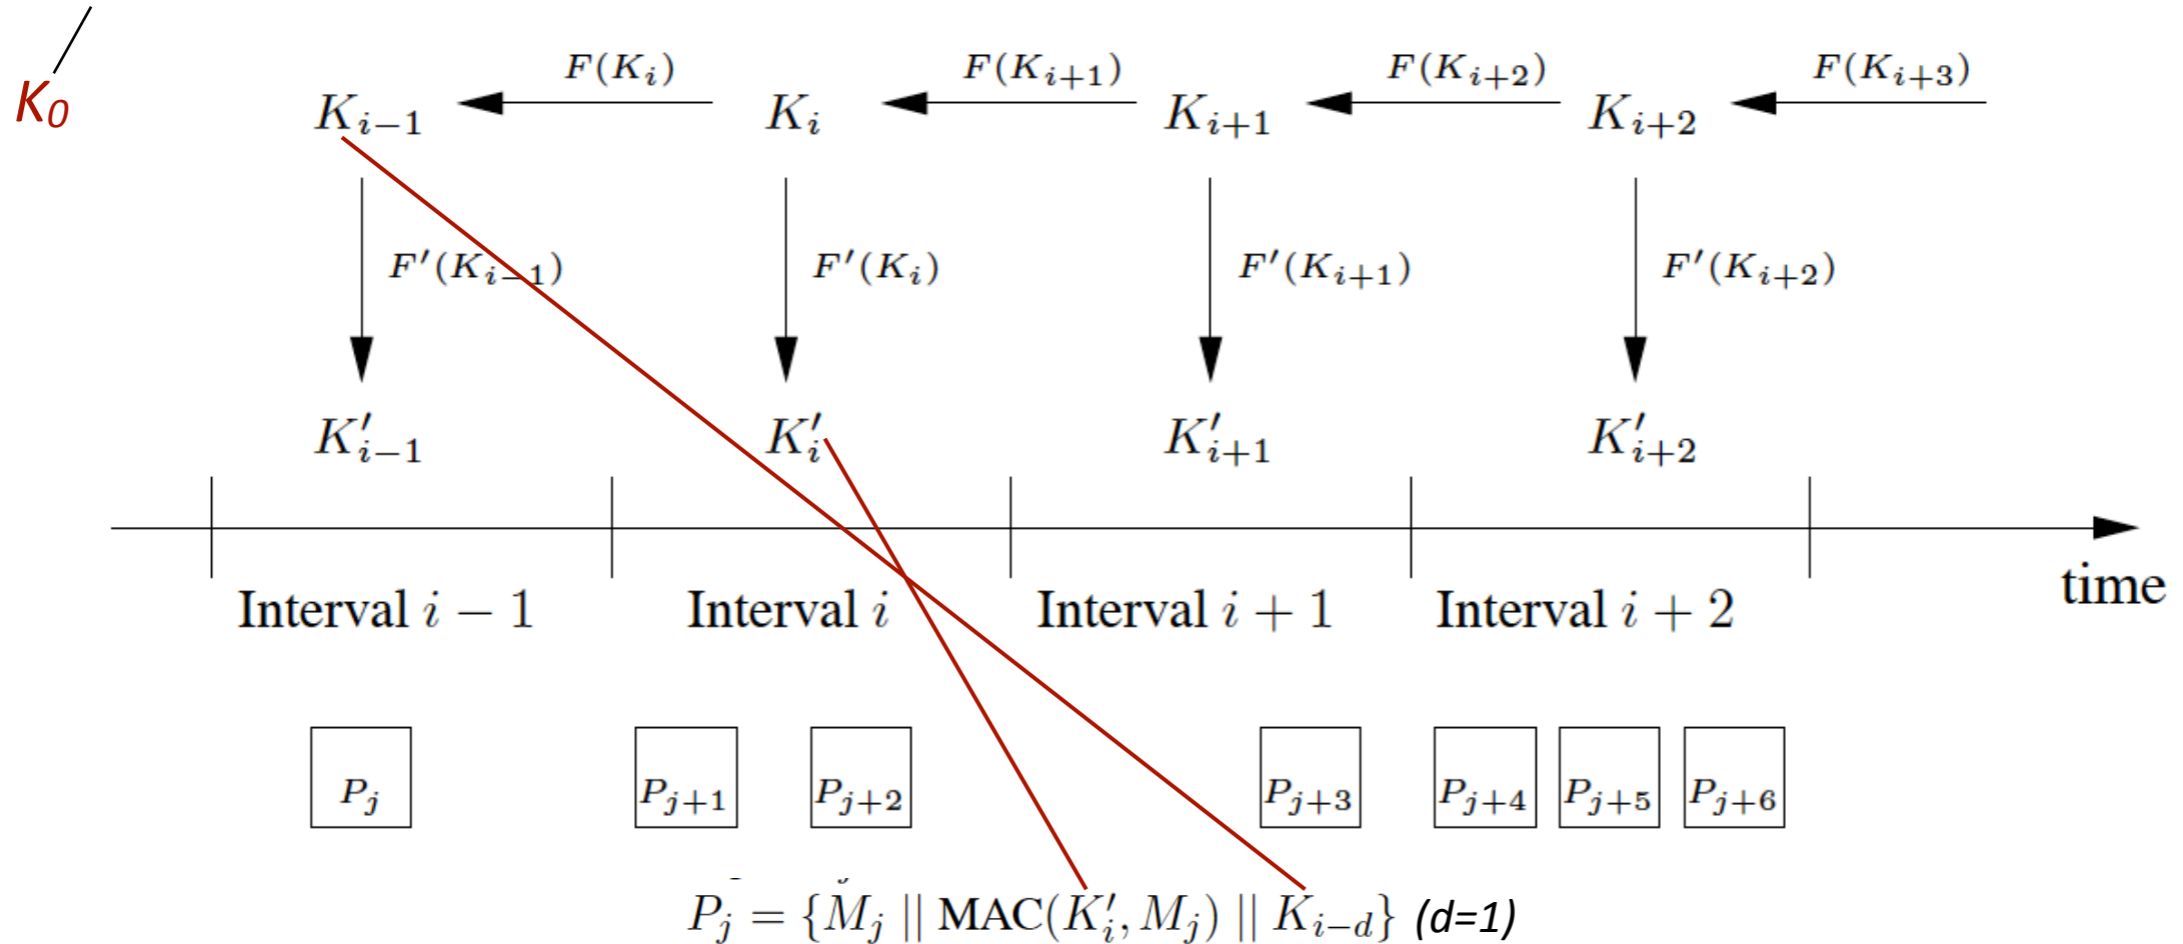

# Question 4 (Tesla)

Question 4.1: Explain packet construction  $P_j = \{M_j \parallel \text{MAC}(K_i', M_j) \parallel K_{i-d}\}$  in the Tesla. How does receiver verify the authenticity of packet  $P_j$ ?

Answer 4.1:

# Broadcast Authentication based on Delayed Key Disclosure (TESLA)

*distributed (authentically) to all receivers  
like a public key of the sender*

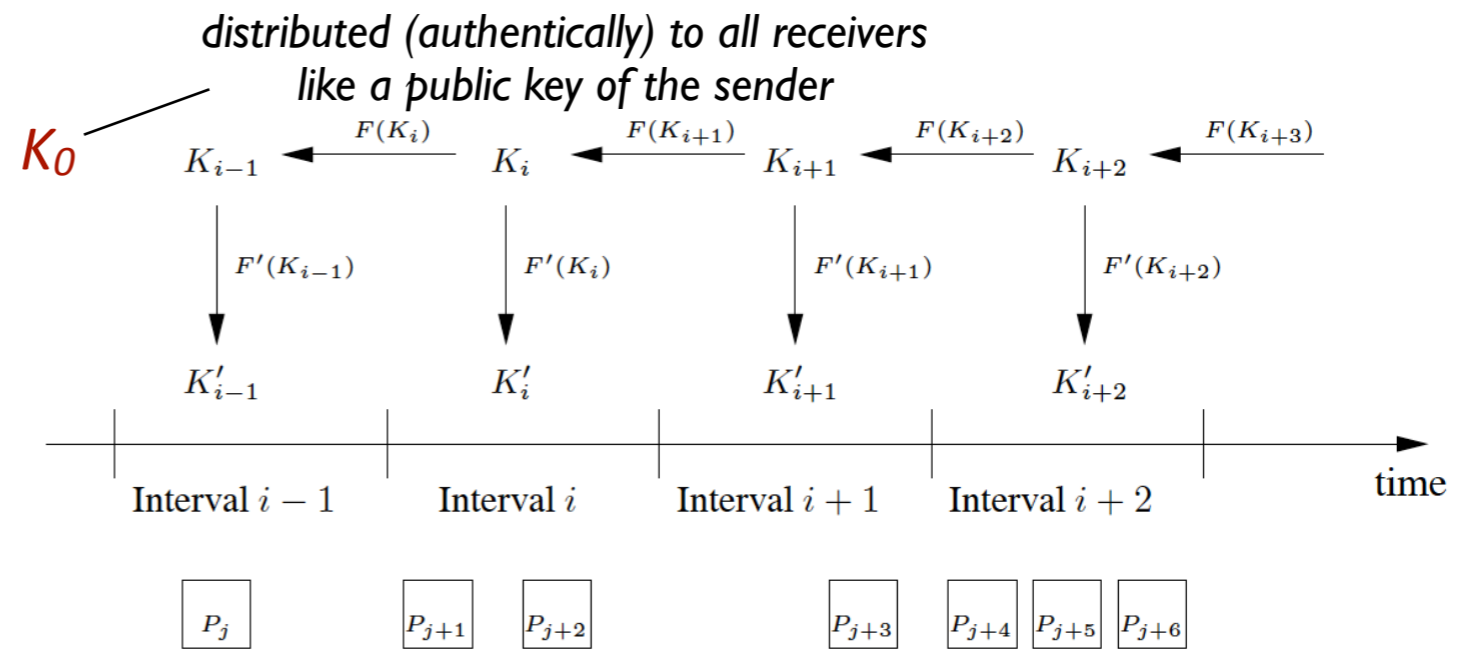

- To transmit a message  $M_j$ , the sender MAC's  $M_j$  with the key of the current time interval ( $K'_i$ )
- The key is used **ONLY WITHIN ITS INTERVAL**
- Each key is **explicitly disclosed in cleartext after the interval**

# Broadcast Authentication based on Delayed Key Disclosure (TESLA)

## Message Verification:

- Receive  $M_j$
- Receive  $K_i$
- Compute  $K'_i = F'(K_i)$
- Verify MAC
- Verify that  $F^n(K_i) = K_0$
- *Verify that the message was received within the key validity interval (before the key was disclosed)*

$$P_j = \{\check{M}_j \parallel \text{MAC}(K'_i, M_j) \parallel K_{i-d}\}$$

- The keys are authenticated using one-way hash chains
- The messages are authenticated using the keys
- If the key is used after the interval, the message is ignored

# Question 5 (Friendly Jamming)

Question 5.1: Suppose devices J and D are using friendly jamming to communicate in the presence of an attacker. How can an attacker separate the signal and noise in the following scenarios:

- a)  $DJ > \lambda/2$
- b)  $DJ \gg \lambda/2$
- c)  $DJ < \lambda/2$

Answer 5.1:

# Friendly Jamming

- Jamming signal is much stronger and covers the spectrum of the data signal.
- If  $DJ > \lambda/2$ , attacker equipped with two antennas can separate signals from J and D (different channels).
- If  $DJ \gg \lambda/2$  attacker can use directional antennas to separate the signals.
- $\Rightarrow$  the only “safe” case seems to be when  $DJ < \lambda/2$

# Lessons learned

- Using Jamming for confidentiality is not without risk
  - MIMO-like attacker can retrieve data despite  $DJ < \lambda/2$ .
  - The attack works from many locations (with some post-processing).
  - The attack can be effective even when jammer and source are mobile.
- Note: Friendly Jamming works well for access control.

# Question 6

Question 6.1: What is spatial diversity?

Question 6.2: What does the term jamming margin refer to?

# Question 7

Question 7.1: Why is a handshake alone sufficient to break the password in the WPA protocol?

Question 7.2: Why are broadband signalling schemes (e.g., DSSS) more difficult to jam? Would DSSS be effective against Wideband jammers?
