1 Introduction

When solving time-dependent Maxwell's equations in two dimensions, the differential equation

$$\begin{aligned}\operatorname{curl} \operatorname{curl} \mathbf{E}(\mathbf{x}) + \tau \mathbf{E}(\mathbf{x}) &= \mathbf{f}(\mathbf{x}), \quad \tau > 0, \quad \mathbf{x} \in \Omega \subset \mathbb{R}^2 \\ \mathbf{E}(\mathbf{x}) \times \mathbf{n}(\mathbf{x}) &= 0, \quad \mathbf{x} \text{ on } \partial\Omega\end{aligned}$$

has to be solved in each time step [1]. Discretizing the equation with the finite edge element method described in section 2 results in a linear system $\mathbf{A}\mathbf{x} = \mathbf{b}$, with \mathbf{A} symmetric, positive definite and sparse. This system can then be solved by a standard linear solver like e.g. the conjugate gradient method (CG). The main problem of this strategy is that the condition number of the matrix \mathbf{A} scales like h^{-2} for shape-regular and quasi-uniform meshes, where h is the length of an element edge. This deteriorates the convergence of the CG method for $h \rightarrow 0$, since

$$\frac{\|\mathbf{e}^k\|_A}{\|\mathbf{e}^0\|_A} \leq 2 \left(\frac{\sqrt{\chi(\mathbf{A})} - 1}{\sqrt{\chi(\mathbf{A})} + 1} \right)^k,$$

where $\chi(\mathbf{A})$ is the condition number of the matrix \mathbf{A} and \mathbf{e}^k the error in the k^{th} step.

The goal of this diploma thesis is to test and to analyse a method for preconditioning the system to obtain a CG convergence rate independent of the system size. This is done by applying the 'Auxiliary Space Method' proposed by Xu ([2],[3]) as it is described in section 3. The main idea of this method is the transfer of the problem to a regular auxiliary mesh where it can be solved or preconditioned in a more efficient way by multigrid methods. This is known to work for standard finite elements and is tested for edge elements in this diploma thesis.

The main focus lies on the scaling properties of the method for shape-regular and quasi-uniform meshes: the effort to solve the linear system should scale linearly with the system size. The computational costs of the critical ingredients of the algorithm are analysed in section 4, where implementation aspects are taken into account.

The numerical results are described in section 5, where properties like condition number, multigrid convergence rate and CG convergence are presented for some test examples.

2 Discretization

2.1 Differential Equation and Variational Formulation

2.1.1 Differential Equation

On a domain $\Omega \in \mathbb{R}^2$, the following differential equation is considered for $\mathbf{u} = \mathbf{u}(\mathbf{x}) = (u_1, u_2)^t \in \mathbb{R}^2$, $\mathbf{x} = (x_1, x_2)^t \in \Omega$:

$$\begin{aligned}\operatorname{curl} \operatorname{curl} \mathbf{u} + \tau \mathbf{u} &= \mathbf{f}, \quad \tau > 0 \\ \mathbf{u} \times \mathbf{n} &= 0, \quad \mathbf{x} \text{ on } \partial\Omega\end{aligned}\tag{1}$$

($\operatorname{curl} \mathbf{u} = \frac{\partial u_2}{\partial x_1} - \frac{\partial u_1}{\partial x_2}$, $\operatorname{curl} \phi = (\frac{\partial \phi}{\partial x_2}, -\frac{\partial \phi}{\partial x_1})^t$, \mathbf{n} : outer unit normal to Ω)

2.1.2 Variational Formulation

Multiplying (1) with a smooth test function $\mathbf{v}(\mathbf{x})$ from the right and integrating over Ω leads to

$$\int_{\Omega} \operatorname{curl} \operatorname{curl} \mathbf{u} \cdot \mathbf{v} \, d\mathbf{x} + \tau \int_{\Omega} \mathbf{u} \cdot \mathbf{v} \, d\mathbf{x} = \int_{\Omega} \mathbf{f} \cdot \mathbf{v} \, d\mathbf{x}, \tag{2}$$

where $\mathbf{a} \cdot \mathbf{b}$ is the euclidean dot product of the vectors \mathbf{a} and \mathbf{b} .

With

$$\begin{aligned}\int_{\Omega} \operatorname{curl} \omega \cdot \mathbf{v} \, d\mathbf{x} &= \int_{\Omega} \frac{\partial \omega}{\partial y} v_1 - \frac{\partial \omega}{\partial x} v_2 \, d\mathbf{x} \\ &= \int_{\partial\Omega} \omega (-v_2, v_1)^t \cdot \mathbf{n} \, d\mathbf{x} + \int_{\Omega} \omega \operatorname{curl} \mathbf{v} \, d\mathbf{x} \\ &= \int_{\partial\Omega} \omega (\mathbf{v} \times \mathbf{n}) \, d\mathbf{x} + \int_{\Omega} \omega \operatorname{curl} \mathbf{v} \, d\mathbf{x} \\ \omega &= \operatorname{curl} \mathbf{u} \quad \text{and} \\ \mathbf{v} \times \mathbf{n} &= \mathbf{0}\end{aligned}$$

it follows that

$$\int_{\Omega} \operatorname{curl} \operatorname{curl} \mathbf{u} \cdot \mathbf{v} \, d\mathbf{x} = \int_{\Omega} \operatorname{curl} \mathbf{u} \operatorname{curl} \mathbf{v} \, d\mathbf{x}.$$

Defining a bilinear form $a(\mathbf{u}, \mathbf{v})$ as

$$a(\mathbf{u}, \mathbf{v}) := \int_{\Omega} \operatorname{curl} \mathbf{u} \operatorname{curl} \mathbf{v} \, d\mathbf{x} + \tau \int_{\Omega} \mathbf{u} \cdot \mathbf{v} \, d\mathbf{x} \tag{3}$$

and a linear functional $f(\mathbf{v})$ as

$$f(\mathbf{v}) := \int_{\Omega} \mathbf{f} \cdot \mathbf{v} \, d\mathbf{x}, \quad (4)$$

for $\mathbf{u}, \mathbf{v} \in H_0(\text{curl}, \Omega) := \{\mathbf{v} : \int_{\Omega} |\mathbf{v}|^2 \, d\mathbf{x} < \infty, \int_{\Omega} |\text{curl } \mathbf{v}|^2 \, d\mathbf{x} < \infty, \mathbf{v} \times \mathbf{n} = \mathbf{0} \text{ on } \partial\Omega\}$ the variational form of (1) reads:

Seek $\mathbf{u} \in H_0(\text{curl}, \Omega)$ with

$$a(\mathbf{u}, \mathbf{v}) = f(\mathbf{v}) \quad \forall \mathbf{v} \in H_0(\text{curl}, \Omega). \quad (5)$$

2.2 Finite Element Spaces

In order to discretize equation (5), we need a finite elements space consisting of a partition of the domain Ω into elements as well as basis functions of a space that approximates $H_0(\text{curl}, \Omega)$. In this work, we always use shape-regular and quasi-uniform triangulations $\mathcal{T}_h = \{T_i\}_i$, consisting of triangles, of the domain $\Omega \subset \mathbb{R}^2$. In contrast to standard finite elements, each edge is equipped with an intrinsic orientation. The space $H_0(\text{curl}, \Omega)$ is approximated with Nédélec's lowest order edge elements [4], which is the following finite element space:

$$\begin{aligned} \mathcal{ND}_1^0(\mathcal{T}_h) &:= \{\mathbf{u}_h \in H_0(\text{curl}, \Omega); \mathbf{u}_{h|T} \in \mathcal{ND}_1(T) \ \forall T \in \mathcal{T}_h\}, \text{ where} \\ \mathcal{ND}_1(T) &:= (\mathcal{P}_0(T))^2 + \{\mathbf{p} \in (\mathcal{P}_1(T))^2; \mathbf{p}(\mathbf{x}) \cdot \mathbf{x} = 0 \ \forall \mathbf{x} \in T\} \\ &= \left\{ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \mapsto \mathbf{a} + b \begin{pmatrix} x_2 \\ -x_1 \end{pmatrix}; \mathbf{a} \in \mathbb{R}^2, b \in \mathbb{R}, \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in T \right\} \end{aligned}$$

($\mathcal{P}_i(T)$ denotes the space of polynomials of degree $< i$ on T .)

The construction of local basis functions on a triangle T (shape functions) and of global basis functions for this finite element space are described in the sections 2.2.1 and 2.2.5.

The discretized problem of (5) then reads:

$$a(\mathbf{u}_h, \mathbf{v}_h) = f(\mathbf{v}_h) \quad \forall \mathbf{v}_h \in \mathcal{ND}_1^0(\mathcal{T}_h). \quad (6)$$

Another finite element space, used in section 3.2.5, is the space of continuous, piecewise linear function on \mathcal{T}_h that vanish on the boundary:

$$S_{1,0}^h(\mathcal{T}_h) := \{\mathbf{v}_h = \sum_{i=1}^{Nv} \alpha_i \lambda_i; \alpha_i \in \mathbb{R}, \lambda_i : \text{hat function of internal vertex } i\} \quad (7)$$

2.2.1 Element Shape Functions

In order to construct a basis of $\mathcal{ND}_1(T)$ for a triangle T , we denote \mathbf{a}_i ($i=1, 2, 3$) the counterclockwise corners of triangle T , e_i the directed edge (fig. 1) between \mathbf{a}_{i+1} and \mathbf{a}_{i+2} (all indices have to be read as mod 3+1) and $\lambda_i^T(\mathbf{x})$ the barycentric coordinate functions of triangle T . Then the shape functions

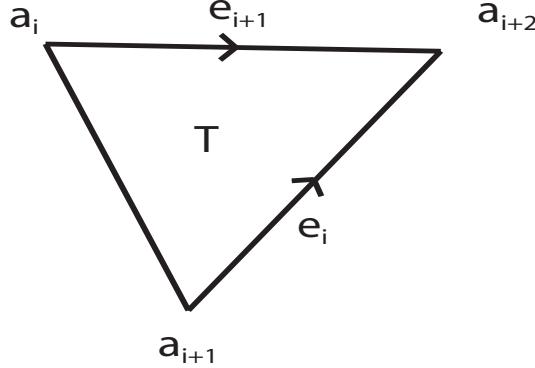

Figure 1: The edge with local index i is opposite the triangle vertex a_i .

$$\mathbf{b}_i^T = \lambda_{i+1} \nabla \lambda_{i+2}^T - \lambda_{i+2}^T \nabla \lambda_{i+1}^T, \quad i = 1, 2, 3$$

form a basis of $\mathcal{ND}_1(T)$. They satisfy:

$$\int_{e_i} \mathbf{b}_j^T \cdot d\mathbf{s} = \begin{cases} \delta_{ij} & \text{if } e_i = [a_{i+1} \ a_{i+2}] \\ -\delta_{ij} & \text{if } e_i = [a_{i+2} \ a_{i+1}]. \end{cases}$$

$\mathbf{u}_h|_T$ can then be written as

$$\mathbf{u}_h|_T = \sum_{j=1}^3 \phi_j^T d_j^T \mathbf{b}_j^T,$$

where d_j provides information about the orientation of edge e_j with respect to triangle T :

$$d_j^T = \begin{cases} 1 & (e_j \text{ counterclockwise directed}) \\ -1 & (\text{otherwise}) \end{cases}$$

$$\Rightarrow \int_{e_i} \mathbf{u}_h|_T \cdot d\mathbf{s} = \sum_j \phi_j^T d_j^T \int_{e_i} \mathbf{b}_j^T \cdot d\mathbf{s} = \phi_i^T.$$

2.2.2 Local Mass Matrix

The second integral of the bilinear form (3), evaluated for all combinations of the shape functions, results in the local mass matrix for triangle T

$$M_{ij}^T = \int_T \mathbf{b}_i^T \cdot \mathbf{b}_j^T d\mathbf{x} = \frac{1}{3}|T| \sum_{k=1}^3 \mathbf{b}_i^T(\mathbf{m}_k) \cdot \mathbf{b}_j^T(\mathbf{m}_k),$$

where \mathbf{m}_k is the midpoint of edge k. Due to linear shape functions, the midpoint rule yields the exact integral.

2.2.3 Local curl curl Matrix

The first part of the bilinear form (3) can also be evaluated exactly for the shape functions. Since these functions are linear, $\operatorname{curl} \mathbf{b}_i^T$ ($i = 1, 2, 3$) is constant ($= c_i$) and from Gauss' Theorem it follows that

$$c_i|T| = \sum_{j=1}^3 d_j^T \int_{e_j} \mathbf{b}_i d\mathbf{x} = \sum_{j=1}^3 d_j^T \delta_{ij} d_j^T = 1$$

which leads to

$$C_{ij}^T = \int_T \operatorname{curl} \mathbf{b}_i^T \operatorname{curl} \mathbf{b}_j^T d\mathbf{x} = c_i c_j |T| = \frac{1}{|T|}.$$

2.2.4 Local Right Hand Side

In order to approximate the local L^2 scalar product of the right hand side function and a shape function, the following one point quadrature rule is used, which yields the exact integral if \mathbf{f} is constant on triangle T:

$$f_i^T = \int_T \mathbf{f} \cdot \mathbf{b}_i^T d\mathbf{x} \approx \frac{|T|}{3} \mathbf{f}(\mathbf{c}_T) \cdot (\nabla \lambda_{i+2}^T - \nabla \lambda_{i+1}^T).$$

(\mathbf{c}_T is the barycenter of triangle T .)

2.2.5 Global Basis Functions and Vector Representation of a Vector Field

If only one single value is assigned to each edge $e \in \mathcal{T}_h$, tangential continuity of the vector field along edges \mathbf{u}_h is forced.

Thus, the degrees of freedom ϕ_e representing a vector field \mathbf{u}_h in the basis

mentioned above can be obtained by evaluating the line integrals along the edges:

$$\phi_e(\mathbf{u}_h) = \int_e \mathbf{u}_h \cdot d\mathbf{s}.$$

Let e be a directed edge with T_1 the triangle on its left and T_2 the triangle

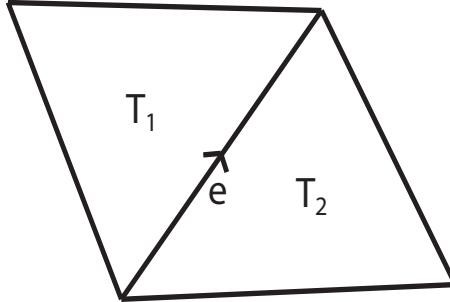

Figure 2: The support of a global basis function \mathbf{b}_e are the two triangles on the left and on the right of the edge.

on its right side. If e is the i^{th} edge of T_1 and the j^{th} edge of T_2 , the global basis function to this edge is (fig. 2):

$$\mathbf{b}_e(\mathbf{x}) = \begin{cases} \mathbf{b}_i^{T_1}(\mathbf{x}), & \mathbf{x} \in T_1 \\ -\mathbf{b}_j^{T_2}(\mathbf{x}), & \mathbf{x} \in T_2 \\ 0, & \text{otherwise} \end{cases}$$

$$\Rightarrow \mathbf{u}_h = \sum_{e \in \mathcal{E}_h} \phi_e \mathbf{b}_e, \quad (8)$$

where \mathcal{E}_h designates the set of inner edges of \mathcal{T}_h .

A vector field $\mathbf{u}_h \in \mathcal{ND}_1^0(\mathcal{T}_h)$ can thus be represented by a vector $\boldsymbol{\phi}_h \in \mathbb{R}^{Ne}$ (Ne : number of inner edges of \mathcal{T}_h).

Let $\mathbf{u}_h(\mathbf{x})$ be represented by $\boldsymbol{\phi}_h$ and $\mathbf{v}_h(\mathbf{x})$ by $\boldsymbol{\psi}_h$. Then the following holds:

$$a(\mathbf{u}_h(\mathbf{x}), \mathbf{v}_h(\mathbf{x})) = \boldsymbol{\phi}_h^t \mathbf{A} \boldsymbol{\psi}_h$$

$$f(\mathbf{v}_h) = \mathbf{f}^t \boldsymbol{\psi}_h$$

(6) is then equivalent to the linear system

$$\mathbf{A} \boldsymbol{\phi}_h = \mathbf{f}. \quad (9)$$

2.2.6 Assembly of Global Stiffness Matrix and Right Hand Side

Let $\mathbf{S}^T \in \mathbb{R}^{N \times 3}$ be the matrix that assigns each edge of triangle T its global edge index:

$$S_{ij}^T = \begin{cases} 1, & \text{global edge } i \text{ is the counterclockwise oriented edge } j \text{ of triangle } T \\ -1, & \text{global edge } i \text{ is the clockwise oriented edge } j \text{ of triangle } T \end{cases}$$

Then \mathbf{A} and \mathbf{f} are assembled as follows:

$$\mathbf{A} = \sum_{T \in T_h} \mathbf{S}^T (\mathbf{C}^T + \tau \mathbf{M}^T) (\mathbf{S}^T)^t \quad (10)$$

$$\mathbf{f} = \sum_{T \in T_h} \mathbf{S}^T \mathbf{f}^T. \quad (11)$$

Boundary conditions ($\mathbf{u} \times \mathbf{n} = 0$) are imposed by neglecting the rows and columns corresponding to the boundary edges.

3 The Auxiliary Space Method

3.1 Theory

The basic idea of the Auxiliary Space Method ([2],[3]) is to transfer a problem to an auxiliary space where it is simpler to solve. The solution in the auxiliary space is then transferred back to the original space. The mismatch between the auxiliary space and the full space is corrected by applying a smoothing scheme.

The auxiliary space method with application to unstructured grids is described in [3]. Given a space \mathcal{V}_h with an inner product $(.,.)$ and symmetric positive definite (SPD) linear operator $\mathcal{A} : \mathcal{V}_h \rightarrow \mathcal{V}_h$, the components necessary for this method are following:

- a “simple” auxiliary space \mathcal{V}_0 with an inner product $[.,.]$,
- a transfer operator $\mathcal{I} : \mathcal{V}_0 \rightarrow \mathcal{V}$ linking the two spaces,
- a representation of the original problem in the auxiliary space, in particular a SPD operator $\mathcal{A}_0 : \mathcal{V}_0 \rightarrow \mathcal{V}_0$,
- an efficient solver in the auxiliary space or a SPD preconditioner operator $\mathcal{B}_0 : \mathcal{V}_0 \rightarrow \mathcal{V}_0$ for the operator \mathcal{A}_0 and
- a smoothing scheme in the original space described by a SPD operator $\mathcal{R} : \mathcal{V}_h \rightarrow \mathcal{V}_h$.

The proposed preconditioner \mathcal{B} with an additive smoother \mathcal{R} then reads:

$$\mathcal{B} = \mathcal{R} + \mathcal{I}\mathcal{B}_0\mathcal{I}^t \quad (12)$$

It is proven [3] that

$$\kappa(\mathcal{B}\mathcal{A}) := \frac{\lambda_{max}(\mathcal{B}\mathcal{A})}{\lambda_{min}(\mathcal{B}\mathcal{A})}$$

is bounded by a constant if the above-mentioned operators fulfil some conditions:

Theorem 1 *If there are some nonnegative constants $\alpha_0, \alpha_1, \lambda_0, \lambda_1$ and β_1 such that $\forall v \in \mathcal{V}_h$ and $w \in \mathcal{V}_0$:*

$$\frac{\alpha_0}{\lambda_{max}(\mathcal{A})}(v, v) \leq (\mathcal{R}v, v) \leq \frac{\alpha_1}{\lambda_{max}(\mathcal{A})}(v, v) \quad (13)$$

$$\lambda_0[w, w]_{A_0} \leq [\mathcal{B}_0\mathcal{A}_0w, w]_{A_0} \leq \lambda_1[w, w]_{A_0} \quad (14)$$

$$||\mathcal{I}w||_A^2 \leq \beta_1 ||w||_{A_0}^2 \quad (15)$$

and if there exists a linear operator $\mathcal{P}: \mathcal{V}_h \rightarrow \mathcal{V}_0$ and positive constants β_0 and γ_0 such that

$$\|\mathcal{P}v\|_{A_0}^2 \leq \frac{\|v\|_A^2}{\beta_0} \quad \text{and} \quad (16)$$

$$\|v - \mathcal{I}\mathcal{P}v\|^2 \leq \frac{\|v\|_A^2}{\gamma_0 \lambda_{max}(A)} \quad (17)$$

then the preconditioner \mathcal{B} satisfies:

$$\kappa(\mathcal{B}\mathcal{A}) \leq (\alpha_1 + \beta_1 \lambda_1) \left(\frac{1}{\alpha_0 \gamma_0} + \frac{1}{\beta_0 \gamma_0} \right) \quad (18)$$

This general technique can now be applied to precondition a problem on an unstructured grid. In [2], such an example is given for the laplace equation with Dirichlet boundary conditions. A structured grid of isosceles rectangular triangles (fig. 4) on $\Omega_0 \subset \Omega$ together with the finite element space of continuous piecewise linear functions that vanish on $\Omega \setminus \Omega_0$ ($S_{1,0}^h(\mathcal{T}_0)$) serves as auxiliary space and the spaces are linked by the standard nodal value interpolants $\mathcal{I}: \mathcal{V}_0 \rightarrow \mathcal{V}_h$ and $\mathcal{P}: \mathcal{V}_h \rightarrow \mathcal{V}_0$.

For this special case (in two dimensions), the inequalities (15) - (17) are rather simple to prove, because for standard nodal value interpolants and $\|v\|_A = \|\nabla v\|_0 \geq \tilde{C} \|v\|_1$ (Poincare inequality), there exists a close relation between the interpolation error $\|v - \mathcal{I}v\|_0$ and the energy norm $\|v\|_A$ (standard error estimate).

For $v \in \mathcal{V}_h, v_0 \in \mathcal{V}_0$ it can be shown that there are constants $C_1 - C_4$ such that

$$\|v_0 - \mathcal{I}v_0\|_0 \leq C_1 h_0 \|v_0\|_1 \quad (19)$$

$$\|\mathcal{I}v_0\|_1 \leq C_2 \|v_0\|_1, \quad (20)$$

$$\|v - \mathcal{P}v\|_0 \leq C_3 h \|v\|_1 \quad (21)$$

$$\|\mathcal{P}v\|_1 \leq C_4 \|v\|_1, \quad (22)$$

where h and h_0 are the mesh sizes of \mathcal{T}_h and \mathcal{T}_0 . Constants for (15) - (17) can then easily be derived. If $h \approx h_0$ it follows that

$$\begin{aligned} \|v - \mathcal{I}\mathcal{P}v\|_0^2 &\leq 2\|v - \mathcal{P}v\|_0^2 + 2\|\mathcal{P}v - \mathcal{I}\mathcal{P}v\|_0^2 \\ &\leq 2C_3^2 h^2 \|v\|_1^2 + 2C_1^2 h^2 \|\mathcal{P}v\|_1^2 \\ &\leq \tilde{C} h^2 \|v\|_1^2. \end{aligned}$$

With $\lambda_{max}(A) \approx h^2$, it follows that there exists a constant for inequality 17. The proofs of (19) - (22) are based on the following inequalities:

$$\|v_0 - \mathcal{I}v_0\|_{0,\infty,T} \lesssim h|v_0|_{1,\infty,T} \text{ (standard error estimate)} \quad (23)$$

$$|v_0|_{1,\infty,\tilde{T}} \lesssim h_0\|v_0\|_{1,\tilde{T}} \text{ (inverse inequality)} \quad (24)$$

$$\sum_{y \in \mathcal{N}_0 \cap \partial\tilde{\Omega}} |v(y)|^2 \lesssim \sum_{x \in \mathcal{N}_h \cap (\Omega \setminus \tilde{\Omega})} |v(x)|^2 \quad (v(y), y \in \mathcal{N}_0 \cap \partial\tilde{\Omega},$$

are convex combinations of $v(x)$, $x \in \mathcal{N}_h \cap (\Omega \setminus \tilde{\Omega})$)

$$\|w\|_{0,\Omega \setminus \tilde{\Omega}} \lesssim h|w|_{1,\Omega \setminus \tilde{\Omega}} \quad \forall w \in H_0^1(\Omega) \quad (26)$$

Notation: \tilde{T} is the union of elements in \mathcal{T}_0 that intersect with T , \mathcal{N}_0 and \mathcal{N}_h are the triangle vertices of \mathcal{T}_0 and \mathcal{T}_h , respectively. $a \lesssim b$ means that there is a constant C with $a \leq Cb$. To prove (19) and (20), the domain Ω is divided into two parts: a domain $\tilde{\Omega}$ of elements in Ω_0 that do not intersect with $\partial\Omega_0$ and the complementary domain $\Omega \setminus \tilde{\Omega}$. Additionally, the subset of $\tilde{\Omega}$ consisting of the interior elements of $\tilde{\Omega}$ is designated with $\hat{\tilde{\Omega}}$ (fig. 3).

Inequality (26) is based on

$$\|w\|_{0,G^\nu}^2 \lesssim \nu^2 \int_{G^\nu} |\nabla w|^2 dx \quad (\text{Poincaré inequality, scaling})$$

(G^ν is a square of side length ν) that holds if w vanishes on one face of G^ν . $\Omega \setminus \tilde{\Omega}$ can then be covered with such squares with $\nu = O(h)$ which leads to (26).

Proof of (19):

$$\begin{aligned} \|v_0 - \mathcal{I}v_0\|_{0,T} &\lesssim \sqrt{|T|} \|v_0 - \mathcal{I}v_0\|_{0,\infty,T} \lesssim h^2 |v_0|_{1,\infty,T} \\ &\lesssim h^2 h_0^{-1} \|v_0\|_{1,\tilde{T}} \lesssim h \|v_0\|_{1,\tilde{T}} \end{aligned}$$

This holds if $h \approx h_0$. ($|T|$ is the area of triangle T .)

$$\begin{aligned} \Rightarrow \|v_0 - \mathcal{I}v_0\|_{0,\Omega}^2 &= \sum_{T \in \mathcal{T}_h} \|v_0 - \mathcal{I}v_0\|_{0,T}^2 \lesssim \sum_{T \in \mathcal{T}_h} h^2 \|v_0\|_{1,\tilde{T}}^2 \\ &\lesssim \sum_{T \in \mathcal{T}_h} h^2 \|v_0\|_{1,T}^2 = h^2 \|v_0\|_1^2 \end{aligned}$$

Proof of (20):

$$\begin{aligned} |v_0 - \mathcal{I}v_0|_{1,T} &\lesssim \sqrt{|T|} |v_0 - \mathcal{I}v_0|_{1,\infty,T} \lesssim h |v_0|_{1,\infty,T} \lesssim h h_0^{-1} |v_0|_{1,\tilde{T}} \\ \Rightarrow \|v_0 - \mathcal{I}v_0\|_1^2 &= |v_0 - \mathcal{I}v_0|_1^2 + \|v_0 - \mathcal{I}v_0\|_0^2 \lesssim h^2 h_0^{-2} |v_0|_1^2 + h^2 \|v_0\|_0^2. \end{aligned}$$

If $h \approx h_0$ and $h \leq C$:

$$\begin{aligned} \Rightarrow \|v_0 - \mathcal{I}v_0\|_1^2 &\lesssim \|v_0\|_1^2 + \|v_0\|_0^2 = \|v_0\|_1^2 \\ \Rightarrow \|\mathcal{I}v_0\|_1 &\leq \|v_0\|_1 + \|v_0 - \mathcal{I}v_0\|_1 \lesssim \|v_0\|_1. \end{aligned}$$

Proof of (21) and (22):

On the interior domain $\tilde{\Omega}$ the same arguments as above can be used to prove

$$\begin{aligned} \|v - \mathcal{P}v\|_{\tilde{\Omega}} &\lesssim h_0 \|v\|_{1,\Omega} \text{ and} \\ \|\mathcal{P}v\|_{\tilde{\Omega}} &\lesssim \|v\|_{1,\Omega}. \end{aligned}$$

For the boundary strip $\Omega \setminus \tilde{\Omega}$ the following holds:

$$|\mathcal{P}v|_{1,\Omega \setminus \tilde{\Omega}}^2 \lesssim \sum_{y \in \mathcal{N}_0 \cap \partial\tilde{\Omega}} |v(y)|^2 \lesssim \sum_{x \in \mathcal{N}_h \cap (\Omega \setminus \tilde{\Omega})} |v(x)|^2 \lesssim |v|_{1,\Omega \setminus \tilde{\Omega}} \lesssim |v|_{1,\Omega}^2.$$

Applying (26) to $\mathcal{P}v$ and v yields

$$\begin{aligned} \|v\|_{0,\Omega \setminus \tilde{\Omega}} &\lesssim h_0 |v|_{1,\Omega \setminus \tilde{\Omega}} \text{ and} \\ \|\mathcal{P}v\|_{0,\Omega \setminus \tilde{\Omega}} &\lesssim h_0 |v|_{1,\Omega \setminus \tilde{\Omega}}. \\ \Rightarrow \|\mathcal{P}v\|_1^2 &= \|\mathcal{P}v\|_{1,\tilde{\Omega}}^2 + \|\mathcal{P}v\|_{1,\Omega \setminus \tilde{\Omega}}^2 \lesssim \|v\|_{1,\Omega}^2 + \|\mathcal{P}v\|_{0,\Omega \setminus \tilde{\Omega}}^2 + |\mathcal{P}v|_{1,\Omega \setminus \tilde{\Omega}}^2 \\ &\lesssim \|v\|_{1,\Omega}^2 + h_0^2 |\mathcal{P}v|_{1,\Omega \setminus \tilde{\Omega}}^2 + |v|_{1,\Omega}^2 \lesssim (2 + h_0^2) \lesssim \|v\|_{1,\Omega}^2 \text{ and} \\ \|v - \mathcal{P}v\| &\leq \|v - \mathcal{P}v\|_{0,\tilde{\Omega}} + \|v\|_{0,\Omega \setminus \tilde{\Omega}} + \|\mathcal{P}v\|_{0,\Omega \setminus \tilde{\Omega}} \leq h_0 \|v\|_{1,\Omega}. \end{aligned}$$

This proves inequalities (21) and (22).

These interpolation operators \mathcal{I} and \mathcal{P} allow a H^1 -stable decomposition in the sense of

$$v = v_h + \mathcal{I}v_0, \quad v_0 = \mathcal{P}v, \quad v_h = v - \mathcal{I}\mathcal{P}v$$

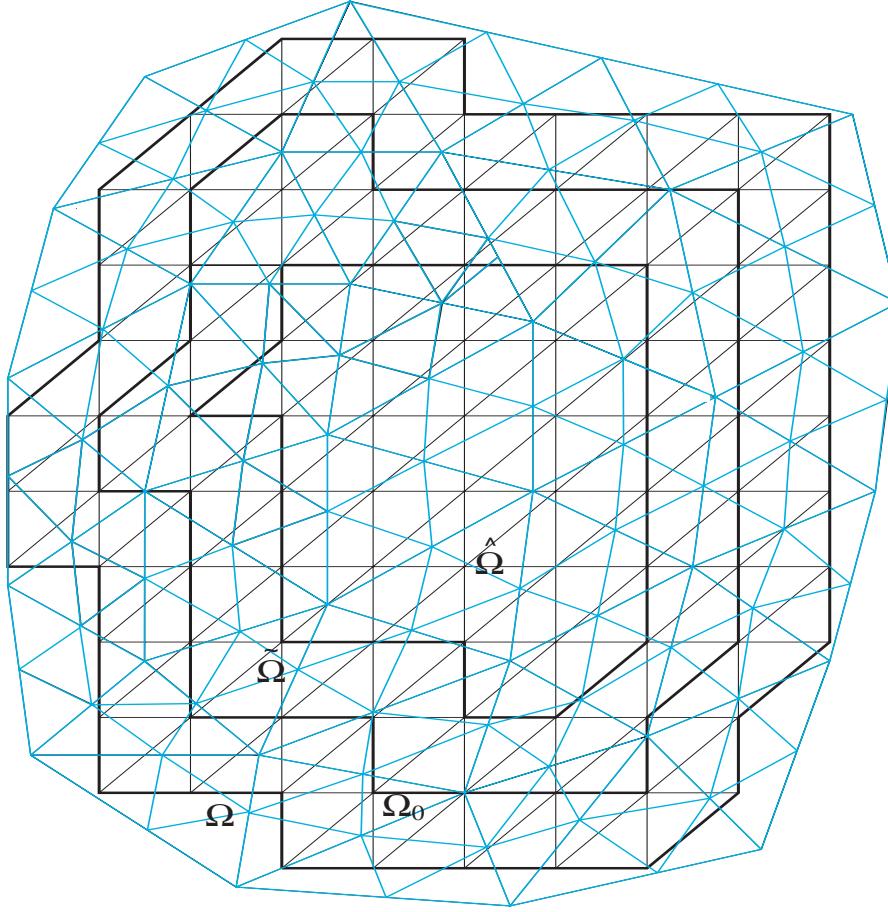

with $h^{-2} \|v_h\|_0^2 + \|w\|_1^2 \lesssim \|v\|_1$. This is sufficient for \mathcal{I} to satisfy the stability condition

$$\inf\{h^{-2} \|\tilde{v}\|_{L^2(\Omega)} + \|w\|_{A_0}^2 : \tilde{v} + \mathcal{I}w = v, \tilde{v} \in \mathcal{V}, w \in \mathcal{V}_0\} \lesssim \|v\|_A \forall v \in \mathcal{V}.$$

3.2 The Auxiliary Space Method for Maxwell's equations

In this work, the method is applied to construct a preconditioner for the problem (6) on a unstructured shape-regular mesh \mathcal{T}_h .

In this section, the required ingredients for the algorithm are defined. The preconditioner on the auxiliary mesh is described in section 3.4 and its application to the CG method in section 3.3. Theoretical aspects are discussed in section 3.5.

Figure 3: The domains Ω , Ω_0 , $\tilde{\Omega}$ and $\hat{\Omega}$.

3.2.1 The Auxiliary Space

The mesh \mathcal{T}_0 on the auxiliary domain $\Omega_0 \subset \Omega$ should have a very simple geometry. Therefore, it consists like in the above-mentioned example of congruent isosceles rectangular triangles of side length dx .

The finite element space $\mathcal{ND}_1^0(\mathcal{T}_0)$ used on this mesh is the same as on the unstructured mesh (see section 2.2).

3.2.2 The Transfer Operator \mathcal{I} from the Auxiliary to the Unstructured Mesh

In order to solve the system $\mathbf{A}\mathbf{x} = \mathbf{f}$ on the auxiliary mesh, the matrix \mathbf{A} and the vector \mathbf{f} have to be transferred to the auxiliary mesh.

Let \mathcal{V}_h and \mathcal{V}_0 be finite element spaces on the unstructured and on the aux-

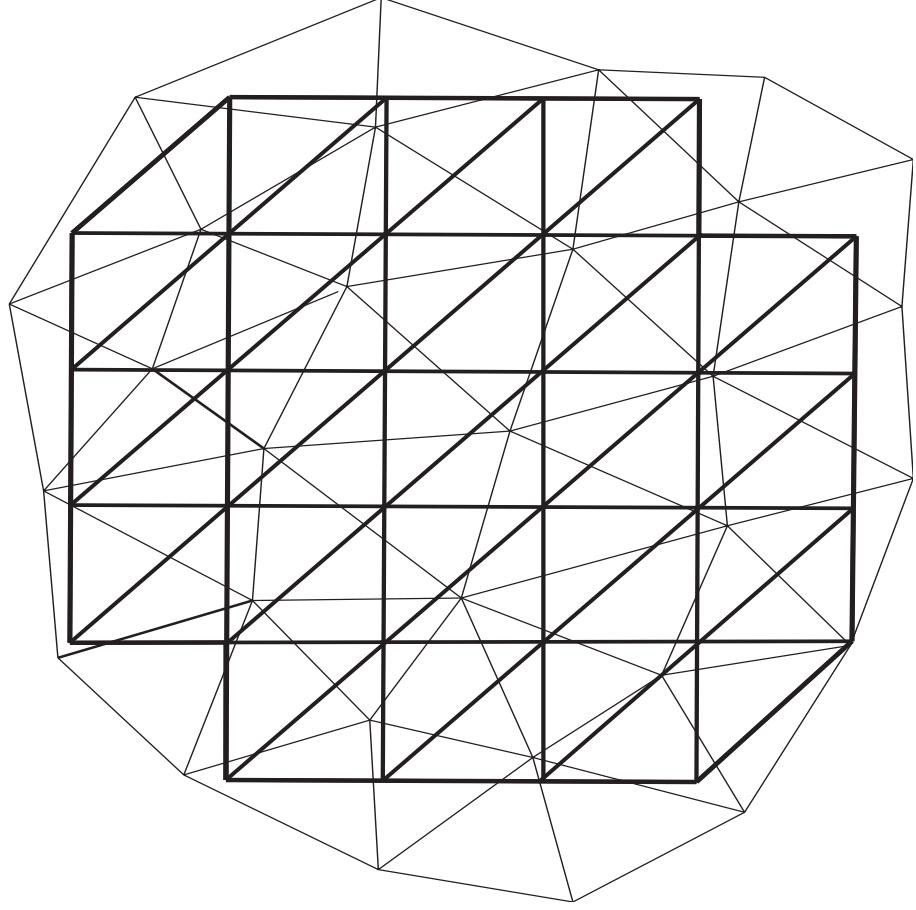

Figure 4: The structured auxiliary mesh.

iliary mesh, respectively, and $\mathcal{E}_h(\mathcal{T}_h)$ the set of internal edges of the unstructured mesh.

The two meshes are linked by the nodal interpolation operator $\mathcal{I} : \mathcal{V}_0 \rightarrow \mathcal{V}_h$ as follows:

$$\mathbf{u}_0 \mapsto \mathbf{u}_h = \mathcal{I}(\mathbf{u}_0) = \sum_{i \in \mathcal{E}_h} \phi_i^h \mathbf{b}_i^h, \quad (27)$$

$$\phi_i^h = \int_{e_i^h} \mathbf{u}_0 \cdot d\mathbf{s}. \quad (28)$$

This linear operator can be expressed as a matrix $\mathbf{I} \in \mathbb{R}^{N e_h \times N e_0}$ with

$$\phi_i^h = \sum_j \mathbf{I}_{ij} \phi_j^0.$$

3.2.3 The Transfer Matrix in the Opposite Direction

Let $\phi^h \in \mathbb{R}^{Ne_h}$ represent a function on the unstructured mesh and $\psi^0 \in \mathbb{R}^{Ne_0}$ a function on the auxiliary mesh. Then, following [2], an operator Π : $\mathbb{R}^{Ne_h} \rightarrow \mathbb{R}^{Ne_0}$ must fulfil the condition

$$(\Pi \phi^h) \cdot \psi^0 = \phi^h \cdot (\mathbf{I} \psi^0) \quad \forall \phi^h \in \mathbb{R}^{Ne_h}, \psi^0 \in \mathbb{R}^{Ne_0},$$

where $\cdot \cdot \cdot$ is the euclidean dot product in \mathbb{R}^{Ne_0} or \mathbb{R}^{Ne_h} , respectively. This implies that

$$\Pi = \mathbf{I}^t.$$

3.2.4 The Linear System in the Auxiliary Space

The linear operator \mathcal{A}_0 in the auxiliary space should correspond in a certain way to the operator \mathcal{A} on the unstructured mesh. In particular, \mathcal{A}_0 should have a similar spectrum like the discretized partial differential operator (see [2]).

There are two fairly natural ways to obtain an operation \mathcal{A}_0 :

- a) Galerkin construction:

$$\mathbf{A}_0 = \mathbf{I}^t \mathbf{A} \mathbf{I}$$

This satisfies

$$(\mathbf{A}_0 \psi^0) \cdot \phi^0 = (\mathbf{I} \psi^0) \cdot (\mathbf{A} \mathbf{I} \phi^0) \quad \forall \phi^0, \psi^0 \in \mathbb{R}^{Ne_0}.$$

- b) Direct computation:

\mathbf{A}_0 is obtained directly from the mesh geometry in the same way as \mathbf{A} on the unstructured mesh (10).

The linear system on the auxiliary mesh then reads:

$$\mathbf{A}_0 \phi_0 = \mathbf{f}_0 \tag{29}$$

with $\mathbf{f}^0 = \mathbf{I}^t \mathbf{f}^h$.

Then $\phi^h = \mathbf{I} \phi^0$ yields a good correction for the solution of the original linear system, if \mathbf{f}_h is the residual.

3.2.5 Smoother

Elementary iterative smoothing schemes for a system $\mathbf{A}\mathbf{x} = \mathbf{b}$ approximate the inverse of \mathbf{A} with a simply invertable matrix \mathbf{B} and iterate

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \mathbf{B}(\mathbf{b} - \mathbf{A}\mathbf{x}_k), \quad k = 1, 2, \dots$$

In the popular Gauss-Seidel method is

$$\mathbf{B} = (\mathbf{D} - \mathbf{L})^{-1},$$

where $\mathbf{A} = \mathbf{D} - \mathbf{U} - \mathbf{L}$ is the decompositioin of the matrix in its diagonal, lower triangular and upper triangular parts.

The Gauss-Seidel method is a good smoother for elliptic problems. But the bilinear form (3) is not elliptic on the kernel $\mathcal{N}(\text{curl})$ of the curl operator and, therefore, a simple Gauss-Seidel smoothing scheme won't work. That's why a more complicated hybrid smoother has to be used [5].

The relaxation scheme used in the precondition algorithm is based on the fact that

$$\text{grad}S_{1,0}^h := \{\mathbf{v}_h = \sum_{i=1}^{Nv} \alpha_i \nabla \lambda_i; \alpha_i \in \mathbb{R}, \lambda_i : \text{hat function of internal vertex } i\}$$

(Nv: number of internal vertices of \mathcal{T}_h)

is a subspace of $\mathcal{ND}_1^0(\mathcal{T}_h)$. In fact, for simply connected Ω ,

$$\text{grad}S_{1,0}^h = \{\mathbf{v}_h \in \mathcal{ND}_1^0(\mathcal{T}_h); \text{curl}(\mathbf{v}_h) = 0\}.$$

If $\mathcal{ND}_1^0(\mathcal{T}_h)$ is decomposed, that is

$$\mathcal{ND}_1^0(\mathcal{T}_h) = \mathcal{N}(\text{curl}) \oplus \mathcal{N}(\text{curl})^\perp,$$

equation (5) can be solved in both subspaces. It turns out that in $\mathcal{N}(\text{curl})^\perp$ the differential equation is purely elliptic and a Gauss-Seidel smoothing scheme can be applied. Furthermore, $\forall \mathbf{u}_h \in \mathcal{N}(\text{curl})$, there is a potential Φ with $\nabla \Phi = \mathbf{u}_h$. In this potential space, equation (5) reads

$$a(\nabla \Phi, \nabla \Psi) = f(\nabla \Psi) \quad \forall \Psi \in \text{grad}S_{1,0}^h(\mathcal{T}_h). \quad (30)$$

Since

$$\begin{aligned} a(\nabla \Phi, \nabla \Psi) &= \int_{\Omega} \text{curl} \nabla \Phi \cdot \text{curl} \nabla \Psi \, d\mathbf{x} + \tau \int_{\Omega} \nabla \Phi \cdot \nabla \Psi \, d\mathbf{x} \\ &= \tau \int_{\Omega} \nabla \Phi \cdot \nabla \Psi \, d\mathbf{x}, \quad \tau > 0 \end{aligned}$$

this bilinear form corresponds to the laplace equation and is therefore elliptic, so after lifting $\mathbf{u}_h \in \mathcal{N}(\text{curl})$ into potential space, it can be smoothed with a Gauss-Seidel scheme.

There is a simple discrete gradient operator $\mathcal{T}: S_{1,0}^h \rightarrow \text{grad}S_{1,0}^h \subset \mathcal{ND}_1^0(\mathcal{T}_h)$ that allows to tranfer a vector $\boldsymbol{\alpha} \in \mathbb{R}^{Nv}$ representing $\Phi \in S_{1,0}^h$ to a vector $\boldsymbol{\phi} \in \mathbb{R}^{Ne}$ representing $\nabla\Phi \in \mathcal{ND}_1^0(\mathcal{T}_h)$:

$$\begin{aligned}\Phi|_T(x) &= \sum_{i=1}^{Nv} \alpha_i \lambda_i(\mathbf{x}) \\ \Rightarrow \nabla\Phi|_T(x) &= \sum_{i=1}^{Nv} \alpha_i \nabla \lambda_i(\mathbf{x}) \\ &\stackrel{!}{=} \sum_{j=1}^{Ne} \phi_j \mathbf{b}_j(\mathbf{x}) \quad \forall \mathbf{x} \in \Omega_h.\end{aligned}\tag{31}$$

If e_{ij} is the directed edge $[\mathbf{a}_i \ \mathbf{a}_j]$, this leads to

$$\phi_{ij} = \alpha_j - \alpha_i \quad (\text{fig. 5}).$$

In global matrix representation the operator $\mathbf{T} \in \mathbb{R}^{Ne \times Nv}$ reads

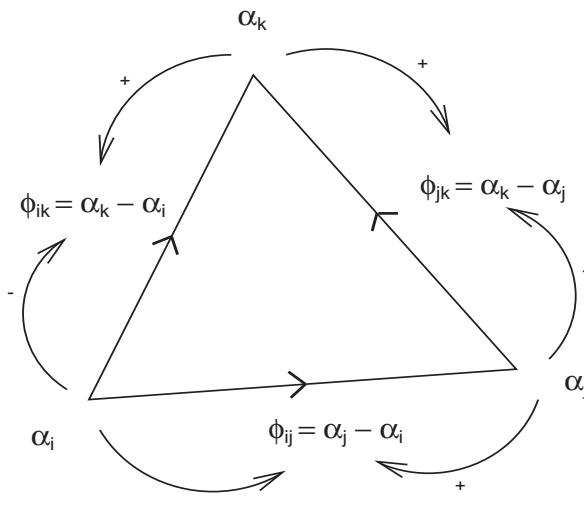

Figure 5: The discrete gradient operator.

$$\mathbf{T}_{i,j} = \begin{cases} 1, & \text{if } \mathbf{a}_j \text{ is end point of edge } i \\ -1, & \text{if } \mathbf{a}_j \text{ is starting point of edge } i \\ 0, & \text{otherwise.} \end{cases}$$

Equation (30) can then be transformed to the linear system as follows:

$$\mathbf{T}^t \mathbf{A} \mathbf{T} \mathbf{x} = \mathbf{T}^t \mathbf{f}. \quad (32)$$

Unfortunately, there exists no reasonable numerical FE space of $\mathcal{N}(\text{curl})^\perp$. Therefore, $\mathcal{ND}_1^0(\mathcal{T}_h)$ is used as an approximation of $\mathcal{N}(\text{curl})^\perp$.

In practice, the system is smoothed on $\mathcal{ND}_1^0(\mathcal{T}_h)$ with a subspace correction on $\text{grad}S_{1,0}^h$.

Given an initial guess $\mathbf{x}_0 \in \mathcal{ND}_1^0(\mathcal{T}_h)$, the hybrid smoothing algorithm is as follows:

$\mathbf{x} = \text{HYBRID_SMOOTHER}(\mathbf{x}_0, \mathbf{f}, n_1, n_2, n_3)$:

1. Pre-smoothing:

n_1 Gauss-Seidel iterations on $\mathcal{ND}_1^0(\mathcal{T}_h)$ with matrix \mathbf{A} and right hand side \mathbf{f}

2. Lifting of the residual to the subspace $\text{grad}S_{1,0}$ with matrix \mathbf{T} :

$$\mathbf{r}_{pot} = \mathbf{T}^t (\mathbf{f} - \mathbf{A} \mathbf{x}).$$

3. Lifting of the matrix \mathbf{A} to the potential space by means of a galerkin construction:

$$\mathbf{A}_{pot} = \mathbf{T}^t \mathbf{A} \mathbf{T}.$$

4. Smoothing in potential space:

n_2 Gauss-Seidel iterations to solve the system

$$\mathbf{A}_{pot} \mathbf{e}_{pot} = \mathbf{r}_{pot}$$

with initial guess $\mathbf{e}_{pot} = 0$.

5. Inverse lifting of \mathbf{e}_{pot} to $\mathcal{ND}_1^0(\mathcal{T}_h)$:

$$\mathbf{e} = \mathbf{T} \mathbf{e}_{pot}.$$

6. Adding the correction to the solution

$$\mathbf{x} = \mathbf{x} + \mathbf{e}.$$

7. Post-smoothing: n_3 Gauss-Seidel iterations on $\mathcal{ND}_1^0(\mathcal{T}_h)$ with matrix \mathbf{A} and right hand side \mathbf{f} .

3.3 Preconditioned CG based on the Auxiliary Space Method

Since the condition number of the matrix \mathbf{A} scales like h^{-2} , the CG scheme converges very slowly when the size of the elements is scaled down. Therefore it is necessary to precondition the system $\mathbf{A}\mathbf{x} = \mathbf{f}$ with a SPD operator \mathbf{B} by solving the equivalent system: $\mathbf{B}\mathbf{A}\mathbf{x} = \mathbf{B}\mathbf{f}$. This can speed up the convergence of the scheme drastically, since

$$\frac{\|\mathbf{e}^k\|_A}{\|\mathbf{e}^0\|_A} \leq 2 \left(\frac{\sqrt{\chi(\mathbf{B}\mathbf{A})} - 1}{\sqrt{\chi(\mathbf{B}\mathbf{A})} + 1} \right)^k.$$

A good preconditioner $\mathbf{B} : \mathbb{R}^{Ne} \rightarrow \mathbb{R}^{Ne}$ for the linear system $\mathbf{A}\mathbf{v} = \mathbf{f}$ approximates the inverse of the matrix \mathbf{A} as well as possible but is computationally cheap. The preconditioner (12) proposed by Xu meets these requirements, if the transfer between the two spaces and the preconditioner in the auxiliary space as well as the smoothing scheme in the original space are computationally cheap. In this work, a multiplicative Gauss-Seidel scheme is used instead of an additive smoother. The general algorithm for the linear operator \mathbf{B} then reads:

$$\mathbf{x} = \mathbf{B}(\mathbf{v}) :$$

1. Initialize $\mathbf{x} = \mathbf{0}$.
2. Pre-smoothing on the unstructured mesh with matrix \mathbf{A} and right hand side \mathbf{v} :

$$\mathbf{x} = \text{PRE_SMOOTHER}(\mathbf{x}).$$

3. Transfer of residual $\mathbf{r} = \mathbf{v} - \mathbf{A}\mathbf{x}$ to the auxiliary mesh:

$$\mathbf{r}_0 = \mathbf{I}^t \mathbf{r}.$$

4. The system $\mathbf{A}_0 \mathbf{e}_0 = \mathbf{r}_0$ is solved using an efficient solver in the auxiliary space or a preconditioner \mathbf{B}_0 is applied:

$$\mathbf{e}_0 = \mathbf{B}_0 \mathbf{r}_0.$$

5. Transfer of the correction to the unstructured mesh:

$$\mathbf{e} = \mathbf{I} \mathbf{e}_0.$$

6. Adding the correction to the solution

$$\mathbf{x} = \mathbf{x} + \mathbf{e}.$$

7. Post-smoothing on the unstructured mesh with matrix \mathbf{A} and right hand side \mathbf{v} :

$$\mathbf{x} = \text{POST_SMOOTHER}(\mathbf{x}).$$

3.3.1 Pre- and Post-Smoothing

Pre-and Postsmothing on the unstructured mesh is used to resolve what cannot be resolved on the auxiliary mesh.

The elementary smoothing schemes for the linear system $\mathbf{A}\mathbf{v} = \mathbf{f}$ applied in the hybrid smoother (section 3.2.5) are the *Forward Gauss-Seidel* method

$$\mathbf{v}_{k+1} = \mathbf{v}_k + (\mathbf{D} - \mathbf{L})^{-1}(\mathbf{f} - \mathbf{A}\mathbf{v}_k), \quad k = 1, 2, \dots$$

with error propagation

$$\mathbf{e}_{k+1} = (\mathbb{I} - (\mathbf{D} - \mathbf{L})^{-1}\mathbf{A})\mathbf{e}_k$$

and the *Backward Gauss-Seidel* method

$$\begin{aligned} \mathbf{v}^{k+1} &= \mathbf{v}^k + (\mathbf{D} - \mathbf{U})^{-1}(\mathbf{f} - \mathbf{A}\mathbf{v}^k), \quad k = 1, 2, \dots \\ \mathbf{e}^{k+1} &= (\mathbb{I} - (\mathbf{D} - \mathbf{U})^{-1}\mathbf{A})\mathbf{e}^k, \end{aligned}$$

where \mathbb{I} designates the identity matrix.

Due to the fact that the auxiliary mesh is smaller than the unstructured mesh and therefore, the Dirichlet boundary conditions on the auxiliary mesh induce errors near the boundary, smoothing is more important there and a restricted smoothing scheme in the subspace of the degrees of freedom in the boundary region is applied: Let $\mathbf{v}_1 \in \mathbb{R}^{n_1}$ be the restriction of $\mathbf{v} \in \mathbb{R}^{n_1+n_2}$ to the boundary region, $\mathbf{v}_2 \in \mathbb{R}^{n_2}$ the restriction to the inner domain and

$\tilde{\mathbf{A}}_1 \in \mathbb{R}^{n_1 \times n_1}$, $\tilde{\mathbf{A}}_2 \in \mathbb{R}^{n_1 \times n_2}$ the straightforward restrictions of \mathbf{A} . Then the *Forward Boundary Gauss-Seidel* iteration is

$$\begin{aligned}\mathbf{v}_1^{k+1} &= \mathbf{v}_1^k + (\tilde{\mathbf{D}}_1 - \tilde{\mathbf{L}}_1)^{-1} [\mathbf{f}_1 - \tilde{\mathbf{A}}_1 \mathbf{v}_1^k - \tilde{\mathbf{A}}_2 \mathbf{v}_2^k] \\ \mathbf{v}_2^{k+1} &= \mathbf{v}_2^k \\ \mathbf{e}^{k+1} &= \begin{pmatrix} \tilde{\mathbb{I}}_1 - (\tilde{\mathbf{D}}_1 - \tilde{\mathbf{L}}_1)^{-1} \tilde{\mathbf{A}}_1 & \mathbf{0} \\ \mathbf{0} & \tilde{\mathbb{I}}_2 \end{pmatrix} \mathbf{e}^k.\end{aligned}$$

and the *Backward boundary Gauss-Seidel* scheme reads

$$\begin{aligned}\mathbf{v}_1^{k+1} &= \mathbf{v}_1^k + (\tilde{\mathbf{D}}_1 - \tilde{\mathbf{U}}_1)^{-1} [\mathbf{f}_1 - \tilde{\mathbf{A}}_1 \mathbf{v}_1^k - \tilde{\mathbf{A}}_2 \mathbf{v}_2^k] \\ \mathbf{v}_2^{k+1} &= \mathbf{v}_2^k \\ \mathbf{e}^{k+1} &= \begin{pmatrix} \tilde{\mathbb{I}}_1 - (\tilde{\mathbf{D}}_1 - \tilde{\mathbf{U}}_1)^{-1} \tilde{\mathbf{A}}_1 & \mathbf{0} \\ \mathbf{0} & \tilde{\mathbb{I}}_2 \end{pmatrix} \mathbf{e}^k\end{aligned}$$

When using a smoother with error propagation \mathbf{M}_o in the original space and a smoother with propagation matrix \mathbf{M}_p in potential space, the error propagation for the hybrid smoother is

$$\mathbf{e}^{k+1} = \mathbf{M}_o^{n_3} (\mathbb{I} - \mathbf{T} \mathbf{M}_p^{n_2} \mathbf{A}_0^{-1} \mathbf{T}^t \mathbf{A}) \mathbf{M}_o^{n_1} \mathbf{e}^k. \quad (33)$$

To meet the symmetry requirement of the operator \mathbf{B} , the pre- and post-smoothing scheme must fulfil certain conditions. Let $\mathbf{M} := \mathbb{I} - \mathbf{B} \mathbf{A}$ denote the error propagation operator of the preconditioner. Then

$$\mathbf{B} \text{ symmetric } \Leftrightarrow \mathbf{A} \mathbf{M} = \mathbf{M}^t \mathbf{A} \text{ for } \mathbf{A} \text{ symmetric}.$$

If \mathbf{M}_1 is the error propagation of the pre-smoother and \mathbf{M}_2 the error propagation of the post-smoother, the following holds:

$$\begin{aligned}\mathbf{M} &= \mathbf{M}_2 (\mathbb{I} - \mathbf{I} \mathbf{B}_0 \mathbf{I}^t \mathbf{A}) \mathbf{M}_1 \\ \Rightarrow \mathbf{A} \mathbf{M}_2 &= \mathbf{M}_1^t \mathbf{A}.\end{aligned}$$

With

$$\mathbf{M}_1 := \mathbf{M}_o^{n_3} (\mathbb{I} - \mathbf{T} \mathbf{M}_p^{n_2} \mathbf{A}_0^{-1} \mathbf{T}^t \mathbf{A}) \mathbf{M}_o^{n_1} \text{ (one hybrid smoother sweep)}$$

it follows that

$$\begin{aligned}\Rightarrow \mathbf{M}_2 &\stackrel{!}{=} \mathbf{A}^{-1} (\mathbf{M}_o^{n_1})^t (\mathbb{I} - \mathbf{A} \mathbf{T} \mathbf{A}_0^{-t} (\mathbf{M}_p^{n_2})^t \mathbf{T}^t) (\mathbf{M}_o^{n_3})^t \\ &= \mathbf{A}^{-1} (\mathbf{M}_o^{n_1})^t \mathbf{A} (\mathbb{I} - \mathbf{T} \mathbf{A}_0^{-t} (\mathbf{M}_p^{n_2})^t \mathbf{T}^t \mathbf{A}) \mathbf{A}^{-1} (\mathbf{M}_o^{n_3})^t \mathbf{A}.\end{aligned}$$

This is fulfilled if in the post hybrid smoother the inverted number of smoothing steps (n_3, n_2, n_1) and inverted Gauss-Seidel iterations with respect to the pre-smoother are used. If several domain and boundary hybrid pre-smoothing sweeps are used, they have to be repeated in inverse order in the post-smoother.

In the numerical examples in section 5 the following pre- and post-smoothers are used:

$\mathbf{x} = \text{PRE_SMOOTHER}(\mathbf{x})$:

$$\begin{aligned}\mathbf{x} &= \text{FORWARD_BOUNDARY_HYBRID_SMOOTHER}(\mathbf{x}, n, n, n) \\ \mathbf{x} &= \text{FORWARD_HYBRID_SMOOTHER}(\mathbf{x}, m, m, m) \\ \mathbf{x} &= \text{FORWARD_BOUNDARY_HYBRID_SMOOTHER}(\mathbf{x}, n, n, n)\end{aligned}$$

$\mathbf{x} = \text{POST_SMOOTHER}(\mathbf{x})$:

$$\begin{aligned}\mathbf{x} &= \text{BACKWARD_BOUNDARY_HYBRID_SMOOTHER}(\mathbf{x}, n, n, n) \\ \mathbf{x} &= \text{BACKWARD_HYBRID_SMOOTHER}(\mathbf{x}, m, m, m) \\ \mathbf{x} &= \text{BACKWARD_BOUNDARY_HYBRID_SMOOTHER}(\mathbf{x}, n, n, n)\end{aligned}$$

3.4 Multigrid Solver/Preconditioner in the Auxiliary Space

In order to obtain an efficient algorithm, the computational costs to solve or precondition the linear system on the auxiliary mesh should be proportional to the system size. A natural approach to achieve this is to use a multigrid scheme. In this case, such a scheme can be understood as a particular kind of the auxiliary space method where a coarser mesh recursively serves as an auxiliary space of the current mesh. On the coarsest mesh the system is solved directly.

3.4.1 Nested Meshes

The meshes are nested in the most natural way: Four triangles of a mesh build one triangle of the next coarser mesh. Triangles of the coarser mesh that are only partly covered by triangles of the finer mesh are neglected. The number of edges so decreases at least by a factor 4 per mesh level.

3.4.2 Restriction and Prolongation

Let $\mathcal{T}_{2^i h}$ ($i = 0, 1, \dots, n$) be the nested grids that contain at least one inner edge. Then the prolongation operator to the next finer grid reads, corre-

sponding to the interpolation operator for the auxiliary space method (section 3.2.2):

$$\begin{aligned} P_{2h}^h : \mathcal{T}_{2h} &\rightarrow \mathcal{T}_h \\ \mathbf{v}_{2h}(\mathbf{x}) &\mapsto \mathbf{v}_h(\mathbf{x}) \\ \phi_i^h &= \int_{e_i^h} \mathbf{v}_{2h} \cdot d\mathbf{s}. \end{aligned}$$

As restriction matrix \mathbf{R}_h^{2h} the transpose of the prolongation matrix is used:

$$\mathbf{R}_h^{2h} = (\mathbf{P}_{2h}^h)^t$$

3.4.3 Multigrid Algorithm

Let $\mathbf{A}_h \mathbf{x}_h = \mathbf{b}_h$ be the linear system to solve on \mathcal{T}_h and \mathbf{x}_{h0} an initial guess for the solution on \mathcal{T}_h . Then the full multigrid algorithm (FMG) reads:

$\mathbf{x}_h = \text{FMG}(\mathbf{x}_{h0}, \mathbf{A}_h, \mathbf{b}_h)$:

If \mathcal{T}_h is the coarsest grid level:

return $\mathbf{x}_h = \mathbf{A}_h \backslash \mathbf{b}_h$

Else:

$\mathbf{x}_h = \mathbf{x}_{h0}$

for MG_cycle_no = 1 : number of multigrid cycles

1. Pre-smoothing on \mathcal{T}_h
 $\mathbf{x}_h = \text{PRE_SMOOTHER}(\mathbf{x}_h)$
2. Restriction of the residual to the coarser grid
 $\mathbf{r}_{2h} = \mathbf{R}_h^{2h}(\mathbf{b}_h - \mathbf{A}_h \mathbf{x}_h)$
3. Coarse grid correction on \mathcal{T}_{2h}
 $\mathbf{e}_{2h} = \text{FMG}(\mathbf{0}_{2h}, \mathbf{A}_{2h}, \mathbf{r}_{2h})$
4. Prolongation
 $\mathbf{e}_h = \mathbf{P}_{2h}^h \mathbf{e}_{2h}$
5. Adding the correction
 $\mathbf{x}_h = \mathbf{x}_h + \mathbf{e}_h$

6. Post-smoothing on \mathcal{T}_h
 $\mathbf{x}_h = \text{POST_SMOOTHER}(\mathbf{x}_h)$

end for

Applying this algorithm to the linear system $\mathbf{A}_0 \mathbf{e}_0 = \mathbf{r}_0$ on the auxiliary mesh provides an approximation $\tilde{\mathbf{e}}_0$ of \mathbf{e}_0 .

Let \mathcal{B}_0 denote the linear operator

$$\begin{aligned}\mathcal{B}_0 & : \mathbb{R}^{Ne} \rightarrow \mathbb{R}^{Ne} \\ \mathcal{B}_0(\mathbf{r}_0) & = \tilde{\mathbf{e}}_0\end{aligned}$$

This operator is symmetric and can be used as a preconditioner for \mathcal{A}_0 .

3.5 Theoretical Upper Bound of the Condition Number

To get an upper bound for the condition number that is independent of the mesh size, constants have to be found that satisfy conditions (13) - (17). If \mathcal{B}_0 is a good preconditioner on the auxiliary space, and \mathbf{R} a good smoother, constants $\alpha_0, \alpha_1, \lambda_0$ and λ_1 can be found.

Problems arise with the proof of a stable decomposition of the space. In contrast to the standard nodal interpolants in the space of $S_{1,0}^h(\Omega)$, \mathcal{ND}_1^0 is not a subspace of H^1 and there is no guarantee for the functions to be continuous. Additionally, although the interpolation operator is the identity operator for linear functions on triangles of the target mesh, it is hard to say what happens to nonlinear and discontinuous functions.

3.5.1 The Operator \mathcal{I}

\mathcal{I} must fulfil the condition

$$\|\mathcal{I}w\|_A^2 \leq \beta_1 \|w\|_{A_0}^2$$

for β_1 independent of the mesh size h . If A_0 is obtained by the means of a galerkin construction, β_1 is equal 1, because

$$\|\mathcal{I}w\|_A^2 = \mathbf{w}^t \mathbf{I}^t \mathbf{A} \mathbf{I} \mathbf{w} = \mathbf{w}^t \mathbf{A}_0 \mathbf{w} = \|w\|_{A_0}^2.$$

If

$$\|w\|_{A_0}^2 := \int_{\Omega_0} \operatorname{curl} w \operatorname{curl} w dx + \tau \int_{\Omega_0} w \cdot w dx$$

it can be shown that

$$\int_{\Omega_h} \operatorname{curl} (\mathcal{I}w) \operatorname{curl} (\mathcal{I}w) dx \leq \int_{\Omega_0} \operatorname{curl} w \operatorname{curl} w dx :$$

Theorem 1 If \mathcal{I} is the interpolation operator described in section 3.2.2 then the following holds:

$$\int_{\Omega_h} \operatorname{curl}(\mathcal{I}w) \operatorname{curl}(\mathcal{I}w) dx \leq \int_{\Omega_0} \operatorname{curl} w \operatorname{curl} w dx$$

Proof:

Let $\tilde{\mathcal{T}}_h$ be a triangulation that is a refinement of \mathcal{T}_h and \mathcal{T}_0 . Then for $T \in \mathcal{T}_h, T^i \subset T, T^i \in \tilde{\mathcal{T}}_h$. From Gauss' theorem it follows that

$$\operatorname{curl}(\mathcal{I}w)|_T = \sum_i \frac{|T^i|}{|T|} \operatorname{curl} w|_{T^i}.$$

With Jensens inequality for the square function and the fact that $\int_{\Omega_h \setminus \Omega_0} \operatorname{curl} w dx = 0$ it follows that

$$\begin{aligned} |\operatorname{curl}(\mathcal{I}w)|_T^2 &\leq \sum_i \frac{|T^i|}{|T|} |\operatorname{curl} w|_{T^i}^2 \\ \Rightarrow \int_{\Omega_h} |\operatorname{curl}(\mathcal{I}w)|^2 dx &= \sum_{T \in \mathcal{T}_h} \int_T |\operatorname{curl}(\mathcal{I}w)|_T^2 dx = \sum_{T \in \mathcal{T}_h} |T| |\operatorname{curl}(\mathcal{I}w)|_T^2 \\ &\leq \sum_{T \in \mathcal{T}_h} \sum_{T^i \subset T} |T^i| |\operatorname{curl} w|_{T^i}^2 = \sum_{T \in \tilde{\mathcal{T}}_h} |T| |\operatorname{curl} w|^2 dx \\ &= \sum_{T \in \tilde{\mathcal{T}}_h} \int_T |\operatorname{curl} w|^2 dx = \int_{\Omega_0} \operatorname{curl} w \operatorname{curl} w dx \end{aligned}$$

This completes the proof.

For the absolute term of the energy norm, no such proof has been found and the numerical results in section 5.6 indicate that possibly none does exist.

3.5.2 The Linear Operator \mathcal{P}

Another problem is the operator \mathcal{P} . A nodal interpolation operator like I causes problems at the boundaries, since the artificial boundary condition creates curl in the boundary stripe of Ω_0 : Let T be a boundary triangle of \mathcal{T}_0 with boundary edge e_1 . If $v \in \mathcal{V}_h$ has vanishing curl, the tangential components on T , α_i , would sum up to zero after nodal interpolation. But if α_1 is set to zero, this creates $|\operatorname{curl}(Pv)|^2$ proportional to $\frac{\alpha_1^2}{|T|^2}$, where α scales like $O(h)$. $\int_{\partial\Omega_0 \times h} |\operatorname{curl} Pv|^2 dx$ then scales like $\frac{1}{h}$.

This problem can be fixed by using a more theoretical operator which is a

nodal interpolation operator inside $\tilde{\Omega}$ (see figure 3). The edge values in the boundary region are then adapted in order to satisfy $\int_{\Omega_0 \setminus \tilde{\Omega}} |\operatorname{curl} Pv|^2 dx \lesssim \int_{\Omega_h \setminus \tilde{\Omega}} |\operatorname{curl} v|^2 dx$.

Let $\partial\tilde{\Omega}$ denote the boundary of this interior domain. Inside this region, the required inequality is fulfilled according to section 3.5.1. The domain $\Omega_0 \setminus \tilde{\Omega}$ is a stripe of width h_0 and its area is approximately $h_0 |\partial\tilde{\Omega}|$. The domain $\Omega_h \setminus \tilde{\Omega}$ is thinner than a stripe of width $2h_0$ and has the approximate area of $\delta h_0 |\partial\tilde{\Omega}|$, $\delta \in [1, 2]$. With Dirichlet boundary conditions and $\int_{\partial\tilde{\Omega}} w \cdot ds = C_1$ it follows that (Green's Theorem)

$$\begin{aligned} \int_{\Omega_h \setminus \tilde{\Omega}} \operatorname{curl} w dx &= C_1 \\ \int_{\Omega_0 \setminus \tilde{\Omega}} \operatorname{curl}(Pw) &= C_1 \end{aligned}$$

If $\operatorname{curl}(Pw)$ is chosen to be constant on $\Omega_0 \setminus \tilde{\Omega}$ this leads to

$$\operatorname{curl}(Pw) = \frac{C_1}{h_0 |\partial\tilde{\Omega}|}.$$

This is approximately possible if the number of triangles in the stripe $\Omega_0 \setminus \tilde{\Omega}$ corresponds to the number of internal edges of this domain. This is fulfilled if the boundary has no fractal structure.

Lets define a constant \tilde{c} as the weighted mean of the curl on the triangles T^i of a triangulation of $\tilde{\Omega}$:

$$\tilde{c} := \sum_i \frac{|T^i|}{|\Omega_h \setminus \tilde{\Omega}|} \operatorname{curl} w|_{T^i}.$$

Then the following holds:

$$\begin{aligned} \delta h_0 \tilde{c}^2 |\partial\tilde{\Omega}| &\approx \int_{\Omega_h \setminus \tilde{\Omega}} \tilde{c}^2 dx \\ &= \sum_i \int_{T^i} \tilde{c}^2 dx \leq \sum_i \int_{T^i} \sum_j \frac{|T^j|}{|\Omega_h \setminus \tilde{\Omega}|} |\operatorname{curl} w|_{T^j}^2 dx \\ &= \sum_i \sum_j \frac{|T^i||T^j|}{|\Omega_h \setminus \tilde{\Omega}|} |\operatorname{curl} w|_{T^j}^2 = \sum_j |T^j| |\operatorname{curl} w|_{T^j}^2 \\ &= \int_{\Omega_h \setminus \tilde{\Omega}} |\operatorname{curl} w|^2 dx \\ \Rightarrow \tilde{c}^2 &\lesssim \frac{1}{\delta h_0 |\Omega_h \setminus \tilde{\Omega}|} \int_{\Omega_h \setminus \tilde{\Omega}} |\operatorname{curl} w|^2 dx \end{aligned}$$

$$\begin{aligned}
\delta |\partial \tilde{\Omega}| h_0 \tilde{c} &\approx \int_{\Omega_h \setminus \tilde{\Omega}} \tilde{c} dx = \sum_j \int_{T_j} \tilde{c} dx \\
&= \sum_j \int_{T_j} \sum_i \frac{|T^i|}{|\Omega_h \setminus \tilde{\Omega}|} \operatorname{curl} w|_{T_i} = \sum_i \sum_j \frac{|T^i||T^j|}{|\Omega_h \setminus \tilde{\Omega}|} \operatorname{curl} w|_{T_j} \\
&= \sum_i |T_i| \operatorname{curl} w|_{T_i} = \int_{\Omega_h \setminus \tilde{\Omega}} \operatorname{curl} w dx = C_1 \\
\Rightarrow \int_{\Omega_0 \setminus \tilde{\Omega}} |\operatorname{curl}(Pw)|^2 &\approx \frac{C_1^2}{h_0 |\partial \Omega|} \approx \delta^2 \tilde{c}^2 |\partial \tilde{\Omega}| h_0 \lesssim \delta^2 \int_{\Omega_h \setminus \tilde{\Omega}} |\operatorname{curl} w|^2 dx
\end{aligned}$$

This justifies the assumption that the curl part of the energy norm scales properly, but no upper bound for the second part has been found.

4 Implementation and Computational Costs

In this section, the implementation aspects of the preconditioner are described. A special emphasis lies on the scaling of storage demands and computational costs with the system size (number of edges or vertices of the unstructured mesh) for all parts of the algorithm. The code is written in Matlab (for details see appendix).

4.1 Data Structures

The two main data structures are an unstructured 2D and a structured 2D mesh. All mesh information is stored in a Matlab struct. This implies information about the mesh geometry as well as other fields related with the mesh like stiffness or interpolation matrix. The 2D structured mesh is an extended unstructured mesh with additional fields describing the relevant part of the mesh where the differential equation is solved.

4.2 Setup of the System

Before applying the preconditioner, all system information that is independent of the right hand side function and algorithm parameters, such as geometries of auxiliary meshes, transfer and stiffness matrices, is computed in advance and stored in the above-mentioned mesh structures. Then the preconditioner can be used by any algorithm, for example the CG scheme.

4.2.1 The Unstructured Mesh

The mesh that covers the computational domain of the problem is generated by an external mesh generator such as femlab and converted to a 2D unstructured mesh where the matrices A and T are assembled. Since all these computations are local, the costs scale linearly with the system size.

4.2.2 Construction of the Auxiliary Meshes

Given an unstructured 2D mesh, the nested submeshes are built up in the following way:

1. Creation of a rectangular mesh that covers the whole domain of the unstructured mesh.

Let $\Delta x \times \Delta y$ be the size of the smallest rectangle that covers the domain of the unstructured mesh and dx the length of a side of the

isosceles triangles on the auxiliary mesh. To simplify the construction of submeshes, there are

$$N_x := \min_{i \in \mathbb{N}} 2^i + 1 > \frac{\Delta x}{dx}$$

vertices in x and

$$N_y := \min_{j \in \mathbb{N}} 2^j + 1 > \frac{\Delta y}{dx}$$

vertices in y direction. This auxiliary mesh domain is not more than four times as large as the smallest rectangle that covers the domain of the unstructured mesh and its storage demands scale linearly with the system size, dependent on the relative size of the triangles of the two meshes and the shape of the unstructured mesh.

2. Determination of the vertices of the structured mesh that are located within the domain of the unstructured mesh. This is done by dividing the area of the auxiliary mesh into boxes and assigning each vertex of both meshes the index of its box. A vertex of the structured mesh can only lie inside a triangle that has at least one vertex inside the same box or inside one of the neighbouring boxes. This leads to a linear scaling with the system size of this classification algorithm.
3. Derivation of the rest of the partial mesh information. Due to pure local computations this again scales linearly with the system size.
4. Recursive submesh construction:
 - Creation of a structured 2D mesh of the same shape as the superordinate one with $N_{x/y} = \frac{N_{x/y}^{sup}-1}{2} + 1$ vertices in x and y direction, respectively.
 - Evaluation of internal vertices by using the known relations between the two structured meshes.
 - Derivation of the rest of the partial mesh information.

Let N_i^{sm} be the number of vertices of the i^{th} structured mesh, $i=1..i_{max}$ (with i_{max} the finest mesh level).

With this recursive mesh definition, the total number of vertices of all submeshes scales linearly with system size:

$$\begin{aligned} N_{i_{max}}^{sm} &= (2^j + 1)(2^k + 1) = 2^{j+k} + 2^j + 2^k + 1 \\ \Rightarrow N_{i_{max}-l}^{sm} &= (2^{(j-l)} + 1)(2^{(k-l)} + 1) \end{aligned}$$

$$\begin{aligned}
\Rightarrow \sum_{l=1}^{i_{max}} N_l^{sm} &= \sum_{l=0}^{i_{max}-1} (2^{(j-l)} + 1)(2^{(k-l)} + 1) \\
&= \sum_{l=0}^{i_{max}-1} 2^{(j+k-2l)} + 2^{(j-l)} + 2^{(k-l)} + 1 \\
&= 2^{j+k} \sum_{l=0}^{i_{max}-1} 2^{-2l} + 2^j \sum_{l=0}^{i_{max}-1} 2^{-l} + 2^k \sum_{l=0}^{i_{max}-1} 2^{-l} + i_{max} \\
&\leq 2^{j+k} \cdot 2 + 2^j \cdot 2 + 2^k \cdot 2 + i_{max} \\
&< 2 \cdot N_{i_{max}}^{sm} + \frac{\log_2(N_{i_{max}}^{sm})}{2} \\
&< \frac{5}{2} N_{i_{max}}^{sm}
\end{aligned}$$

4.2.3 Transfer Matrix I

The transfer of a vector field from the auxiliary mesh to the unstructured mesh is done by evaluating the edge integrals of the vector field on the auxiliary mesh along the edges of the target mesh. In a first step, for each edge of the unstructured mesh all intersections with the auxiliary mesh are computed. Since the edge indices on the structured mesh can be obtained from the coordinates of the end points, the computational costs scale linearly with the number of edges on the unstructured mesh.

The integral over an edge is then computed as the sum over the integrals of the sections:

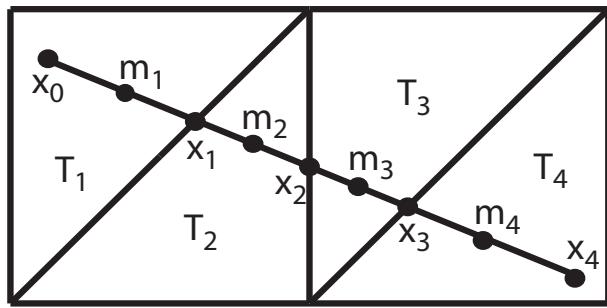

Figure 6: An edge $[x_0 \ x_n]$ on the unstructured mesh is divided into n sections by the auxiliary mesh ($n=4$).

$$\begin{aligned}
\int_{e^{us}} \mathbf{v}^0 \cdot d\mathbf{s} &= \sum_{i=1}^n \mathbf{v}^0(\mathbf{m}_i) \cdot (\mathbf{x}_i - \mathbf{x}_{i-1}) \\
&= \sum_{i=1}^n \sum_{j=1}^{Ne} \alpha_j \mathbf{b}_j^0(\mathbf{m}_i) \cdot (\mathbf{x}_i - \mathbf{x}_{i-1}) \\
&= \sum_{j=1}^{Ne} \sum_{i=1}^n \mathbf{b}_j^0(\mathbf{m}_i) \cdot (\mathbf{x}_i - \mathbf{x}_{i-1}) \alpha_j \\
\Rightarrow \mathbf{I}_{e,j} &= \sum_{i=1}^n \mathbf{b}_j^0(\mathbf{m}_i) \cdot (\mathbf{x}_i - \mathbf{x}_{i-1})
\end{aligned}$$

with $\mathbf{b}_j^0(\mathbf{m}_i) = \mathbf{0}$ if e_j is not an edge of triangle T_i .

This interpolation matrix is obviously sparse if the edges of both meshes have approximately the same length.

4.2.4 Multigrid Transfer Matrices \mathbf{P}_{2h}^h

The known relations between two meshes \mathcal{T}_h and $\mathcal{T}_{2h} \subset \mathcal{T}_h$ allows a very simple computation of the transfer matrix. For an auxiliary mesh with isosceles triangles, the local prolongation matrices for upper triangles (\mathbf{P}_u) and for lower triangles (\mathbf{P}_l) (see figures 7 and 8) read:

$$\mathbf{P}_u = \begin{pmatrix} 0.25 & -0.25 & 0.25 \\ 0 & 0.5 & 0 \\ 0 & 0 & 0.5 \\ 0.5 & 0 & 0 \\ 0 & 0.5 & 0 \\ 0.25 & 0.25 & 0.25 \\ 0.5 & 0 & 0 \\ -0.25 & 0.25 & 0.25 \\ 0 & 0 & 0.5 \end{pmatrix} \quad \mathbf{P}_l = \begin{pmatrix} 0.25 & 0.25 & -0.25 \\ 0 & 0.5 & 0 \\ 0 & 0 & 0.5 \\ 0.5 & 0 & 0 \\ 0.25 & 0.25 & 0.25 \\ 0 & 0 & 0.5 \\ 0.5 & 0 & 0 \\ 0 & 0.5 & 0 \\ -0.25 & 0.25 & 0.25 \end{pmatrix}.$$

The assembly of the global transfer matrix is done by identifying local and global indices on both meshes, a known relation between the closely related meshes.

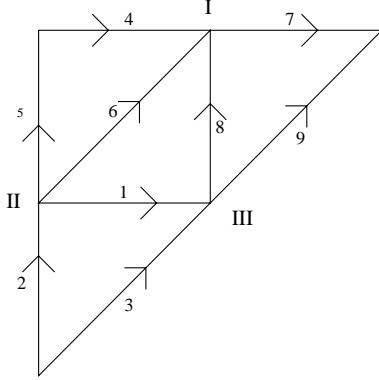

Figure 7: Local edge indices of an upper triangle

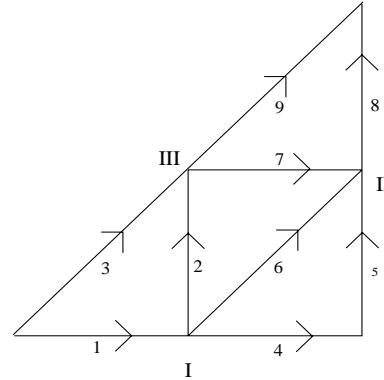

Figure 8: Local edge indices of an lower triangle

4.3 Preconditioner

The preconditioning algorithm consists of transfers of functions from one FE space to another and of smoothing in these spaces.

4.3.1 Transfers and Multigrid

Since all transfers are local, this guarantees linear scaling with the system size. The computational costs of one multigrid cycle scale linearly with the system size if on each level they are proportional to the size of this subsystem. If the computational costs for pre- and post-smoothing and transfers to and from the next coarser grid are proportional to the number number of degrees of freedom, they are approximately $C \cdot 4^i$ on the mesh of level i with system size $N \approx 4^{i_{max}}$. In the V-multigrid scheme, each level is only visited once, so the costs sum up to

$$C_{V\text{-cycle}} = \sum_{i=0}^{i_{max}} C \cdot 4^i < \frac{3}{2} CN \quad (34)$$

$$\gtrsim \frac{5}{4} CN. \quad (35)$$

In the W-multigrid scheme, each level is visited $2^{i_{max}-i+1}$ times which leads to costs of a W-cycle of

$$C_{W\text{-cycle}} = \sum_{i=0}^{i_{max}} C \cdot 4^i \cdot 2^{i_{max}-i+1} = C 2^{i_{max}+1} \sum_{i=0}^{i_{max}} 2^i < 4 C N \quad (36)$$

The total costs to achieve a given precision depends on the scaling of the convergence rate with the system size.

4.3.2 Smoothing

All smoothing schemes used in the algorithm are based on the Gauss-Seidel method. One *Forward Gauss-Seidel* iteration is equivalent to a loop over all indices:

```
for i=1:N
     $v_i = (b_i - \sum_{j \neq i} (A_{ij}v_j)) / A_{ii}$ 
end i
```

(The *Backward Gauss-Seidel* scheme passes through the indices in inverted order.) With \mathbf{A} sparse, this scales linearly with N . If the scheme is only applied to the boundary region, i runs only over the degrees of freedom in the boundary layer and $\lfloor \frac{N}{\# \text{dof in boundary region}} \rfloor$ Gauss Seidel sweeps can be done instead of one sweep over all indices.

5 Numerical Experiments

The quality of the preconditioner depends on two main factors: on the one hand, it is influenced by the accuracy of the transfer of the problem to the auxiliary mesh and the smoothing properties of the hybrid smoother, i.e. the auxiliary space method, and, on the other hand, the quality of the preconditioner in the auxiliary space - in this case the multigrid scheme - is important. For the following experiments the test meshes and the right hand side function described in sections 5.1 and 5.2 are used. Section 5.3 contains the experiments that test the auxiliary space method and section 5.4 those testing the multigrid convergence. Results of the combination of the auxiliary space method with a multigrid preconditioner in the auxiliary space are presented in section 5.5.

5.1 The Unstructured Test Meshes

The numerical experiments are conducted on the meshes that approximate the circle $\Omega := \{\mathbf{x} : |\mathbf{x} - \mathbf{m}| \leq 0.45, \mathbf{m} = (0.5 \ 0.5)^t\}$. The coarsest mesh is shown in figure 9. The meshes II - VI are recursive refinements of this mesh, by dividing each triangle into four subtriangles and adapting the mesh at the boundary.

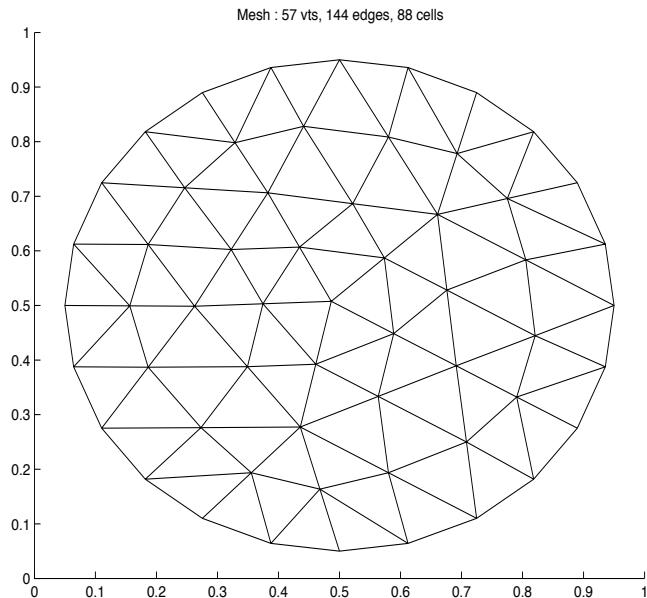

Figure 9: Mesh I

5.2 The Test Function

All tests are performed with the right hand side function

$$\mathbf{f}(\mathbf{x}) = \frac{3}{10|\mathbf{x}|} \begin{pmatrix} x_2 - 0.5 \\ -x_1 - 0.5 \end{pmatrix} + \mathbf{v}(\mathbf{x})$$

with the exact solution (for $\tau = 1$)

$$\mathbf{v}(\mathbf{x}) = \begin{pmatrix} (x_1 - 0.5) + 10 (0.45 - |\mathbf{x}|) \cdot (x_2 - 0.5) \\ (x_2 - 0.5) - 10 (0.45 - |\mathbf{x}|) \cdot (x_1 - 0.5) \end{pmatrix}$$

on the domain $\Omega := \{\mathbf{x} : |\mathbf{x} - \mathbf{m}| \leq 0.45, \mathbf{m} = (0.5 \ 0.5)^t\}$.

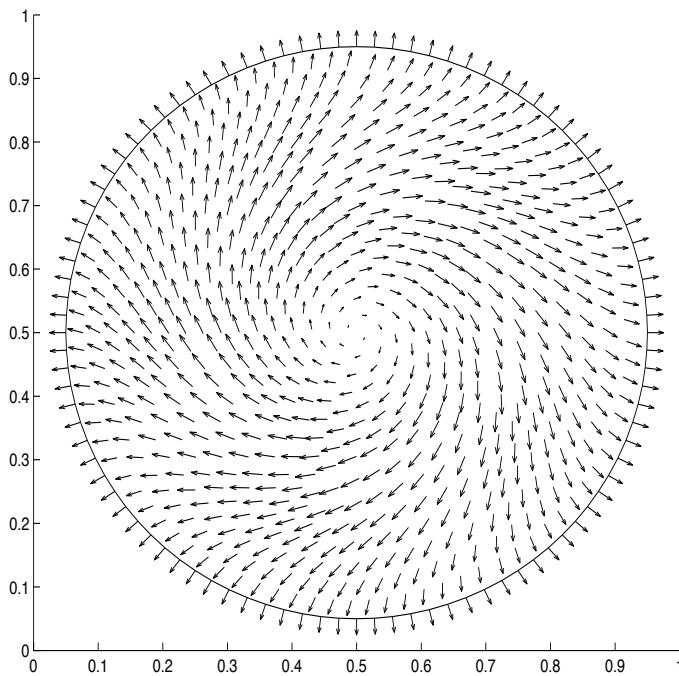

Figure 10: Exact Solution

5.3 Test of the Auxiliary Space Method

In order to test the mesh transfer, the problem on the auxiliary mesh is solved by a direct solver, which is actually not a problem on these rather small test meshes. The condition number of the preconditioned system and

the resulting convergence of the CG scheme are used as indicators of the quality of the auxiliary space method.

The results in section 5.3.4 show the sensitivity of these properties with respect to the smoothing on the unstructured mesh, the relative element size of the unstructured and the auxiliary mesh and the weighting factor τ of the absolute term.

5.3.1 Condition Number

The condition number χ of a regular matrix \mathbf{M} is defined as

$$\chi(\mathbf{M}) := \sqrt{\frac{\max_{\|\mathbf{x}\|_2=1} \|\mathbf{M}^t \mathbf{M} \mathbf{x}\|_2}{\min_{\|\mathbf{x}\|_2=1} \|\mathbf{M}^t \mathbf{M}\|_2}} = \sqrt{\frac{\|\mathbf{M}^t \mathbf{M}\|_2}{\|(\mathbf{M}^t \mathbf{M})^{-1}\|_2}},$$

where $\|\cdot\|_2$ is the euclidean norm.

$\chi(\mathbf{B}\mathbf{A})$ is used as a measure for the quality of the preconditioner \mathbf{B} . $\|(\mathbf{B}\mathbf{A})^t \mathbf{B}\mathbf{A}\|_2 = \|\mathbf{A}\mathbf{B}\mathbf{B}\mathbf{A}\|_2$ and $\|((\mathbf{B}\mathbf{A})^t \mathbf{B}\mathbf{A})^{-1}\|_2 = \|(\mathbf{A}\mathbf{B}\mathbf{B}\mathbf{A})^{-1}\|_2$ are evaluated by (inverse) vector iteration.

Forward Vector Iteration

```

for n = 1,2, ...
     $\mathbf{x}_n$       =       $\mathbf{A}\mathbf{B}\mathbf{B}\mathbf{A}\mathbf{x}_{n-1}$ 
     $\lambda_n$       =       $\frac{\|\mathbf{x}_n\|_2}{\|\mathbf{x}_{n-1}\|_2} \rightarrow \|\mathbf{A}\mathbf{B}\mathbf{B}\mathbf{A}\|_2^2, (n \rightarrow \infty)$ 
     $\mathbf{x}_n$       =       $\frac{\mathbf{x}_n}{\|\mathbf{x}_n\|_2}$ 
end for

```

Inverse Vector Iteration

```

for n = 1,2, ...
     $\mathbf{x}_n$       =       $(\mathbf{A}\mathbf{B}\mathbf{B}\mathbf{A})^{-1}\mathbf{x}_{n-1}$ 
     $\lambda_n$       =       $\frac{|\mathbf{x}_n|}{|\mathbf{x}_{n-1}|} \rightarrow \|(\mathbf{A}\mathbf{B}\mathbf{B}\mathbf{A})^{-1}\|_2^2, (n \rightarrow \infty)$ 
     $\mathbf{x}_n$       =       $\frac{\mathbf{x}_n}{\|\mathbf{x}_n\|_2}$ 
end for

```

The iterations are stopped if

$$\left| \frac{\mathbf{x}_n}{\|\mathbf{x}_n\|} - \frac{\mathbf{x}_{n-1}}{\|\mathbf{x}_{n-1}\|} \right| \leq 1e-5$$

or if $n = 200$ is reached. All vector iterations from which the following condition numbers are computed show reliable convergence with these stop criteria.

5.3.2 CG Convergence in the Energy Norm

There exists an analytical error bound in the energy norm which is directly connected with the condition number $\chi(\mathbf{BA})$ of the preconditioned system [3]:

$$\frac{\|\mathbf{e}^k\|_A}{\|\mathbf{e}^0\|_A} \leq 2 \left(\frac{\sqrt{\chi(\mathbf{BA})} - 1}{\sqrt{\chi(\mathbf{BA})} + 1} \right)^k,$$

where $\mathbf{e}^k = \mathbf{x} - \mathbf{x}_k$ is the error in the k^{th} step.

Based on the condition number, the theoretical upper bound for the number of CG iterations n_{CG} to reduce the error in the energy norm by a factor c is

$$n_{CG} = \frac{\log \frac{c}{2}}{\log \frac{\sqrt{\chi(\mathbf{BA})}-1}{\sqrt{\chi(\mathbf{BA})}+1}}.$$

5.3.3 Computational Costs to Solve the Linear System in Praxis

When solving a linear system with a CG scheme, only the relative residual is available as a measure for the accuracy of the solution and it is used as a stop criterion for the algorithm. Therefore, the number of CG steps to reach a certain relative residual is a reasonable measure for the computational costs to solve a linear system in praxis. In the following section, there are experiments where the number of CG iterations to reach a relative residual of 1e-6 are counted.

5.3.4 Numerical Results

The condition number and the resulting CG convergence is analysed for different system parameters:

- a) Number of domain smoothing sweeps m ($m_1 = m_2 = m_3 = m$)
- b) Number of boundary smoothing sweeps n ($n_1 = n_2 = n_3 = n$) on the edges of which at least one end point belongs to a boundary triangle (one sweep corresponds to $\lfloor \frac{\#\text{dof in domain}}{\#\text{dof in boundary region}} \rfloor$ Gauss Seidel sweeps)

- c) Relative mesh size ms , (ratio of dx (length of a side of a right triangle of the structured mesh) and the mean edge length of the unstructured mesh)
- d) Constant τ in (1)

All these parameters are tested with both variants of the stiffness matrix on the auxiliary mesh, i.e. galerkin construction (G) and direct computation (D).

Tables 1 and 2 show the dependence of the condition number on the number of domain smoothing sweeps. With galerkin construction of the stiffness matrix, the linear system on the auxiliary mesh gets badly conditioned with decreasing element size, so the tests cannot be done on the meshes V and VI. Figure 11 presents the theoretical upper bounds of CG iterations n_{CG} corresponding to the condition numbers in table 1. The number of CG iterations grows logarithmically with the system size for all smoothing parameters. The number of iterations to reduce the relative residual in the euclidean norm by a factor of 1e-6 are presented in tables 3 and 4. Also this number grows slowly with the system size for these test cases.

The results in tables 5 and 6 indicate that it is reasonable to perform one boundary smoothing sweep on the unstructured mesh, whereas table 8 shows that the condition number does not diverge when τ is scaled down. In table 7 is shown how the relative element size of the unstructured mesh and the auxiliary mesh influences the condition number of the preconditioned system whereas figure 12 shows the corresponding number of CG iterations. Since the number of iterations cannot be reduced essentially by scaling down the relative mesh size, 1.0 is a reasonable choice for the relative mesh size.

5.4 Test of the Multigrid Solver in the Auxiliary Space

5.4.1 Numerical Convergence Rate

In order to analyse the scaling properties of the multigrid solver with the system size, the numerical convergence rate q of the residual is used.

$$q_i := \frac{\|\mathbf{f} - \mathbf{A}\mathbf{x}_i\|_2}{\|\mathbf{f} - \mathbf{A}\mathbf{x}_{i-1}\|_2} \rightarrow q$$

with $\mathbf{x}_{i+1} = \text{FMG}(\mathbf{x}_i, \mathbf{A}, \mathbf{f})$ (see section 3.4.3) and $\mathbf{f} = \mathbf{I}^t \mathbf{f}^h$.

5.4.2 Numerical Results

The Dirichlet boundary conditions on the submeshes introduce inaccuracies in the boundary layers. Therefore, additional smoothing iterations are performed in these domains. Figures 13 and 14 show the influence of the width of these layers on the convergence rate for multigrid with V- and W-cycles, respectively. In the following numerical experiments the width of the boundary layer is chosen to be 3.

In table 9 the convergence rates for V-and W-cycle mutigrid are compared for both choices of the stiffness matrix. Like before, 'G' stands for stiffness matrix with galerkin construction and 'D' for direct computation of the stiffness matrix. It is obvious that the galerkin construction works neither with the V- nor with the W-cycle multigrid and therefore, in all the following experiments the stiffness matrix is always computed directly.

The sensitivity of the convergence rate with respect to the number of smoothing sweeps in the domain is shown in table 10. The convergence rate increases with the number of degrees of freedom (number of internal edges) for all choices of m . The dependence of the number of multigrid iterations to reduce the residual by a factor of 1e-16 on the number of degrees of freedom is shown in figure 15. Considering the fact that the costs of a W-multigrid cycle exceeds the costs of a V-cylce by a constant factor of approximately $\frac{16}{5}$, the W-cycle multigrid becomes relatively cheaper with increasing system size. If the results in figure 15 are extrapolated to a larger number of degrees of freedom, the number of iterations for W-cycle multigrid with 5 smoothing sweeps becomes (almost) independent of the system size.

Table 11 shows that the convergence rates do not increase when τ is decreased.

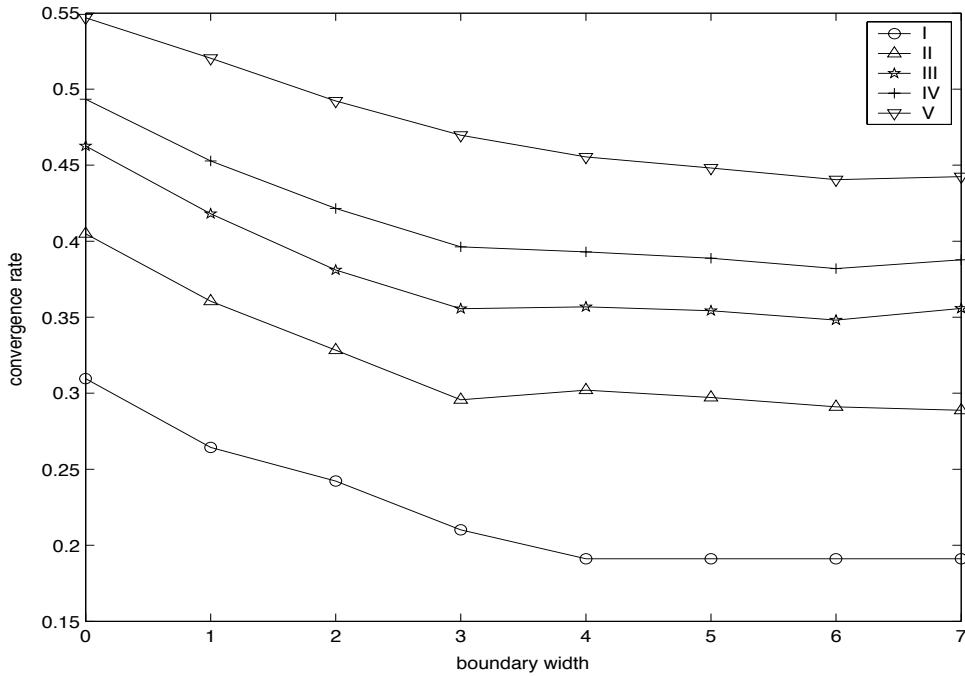

Figure 13: Dependence of the convergence rate of the multigrid V-cycle algorithm on the width of the boundary layer on the meshes I-V.

5.5 Preconditioned CG with Multigrid Solver in the Auxiliary Space

Figures 16 to 19 show the convergence of the preconditioned CG scheme on the test meshes I-VI, when one W-multigrid cycle is applied to precondition the system on the auxiliary mesh. The error in the energy norm ($\|e_k\|_A$) converges independently of the mesh level for meshes above level 3 with both smoothing schemes, so the computational costs to reduce the energy error scale linearly with the system size.

Figure 19 shows that the convergence of the residual in the euklidean norm is almost independent of the system size. The number of smoothing steps influences only the general convergence rate, not the scaling with the system size.

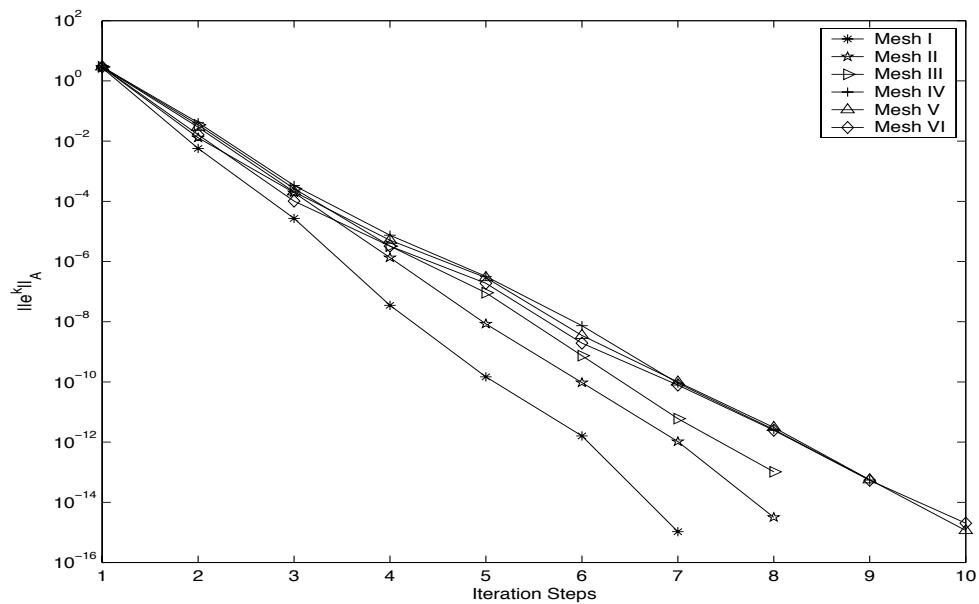

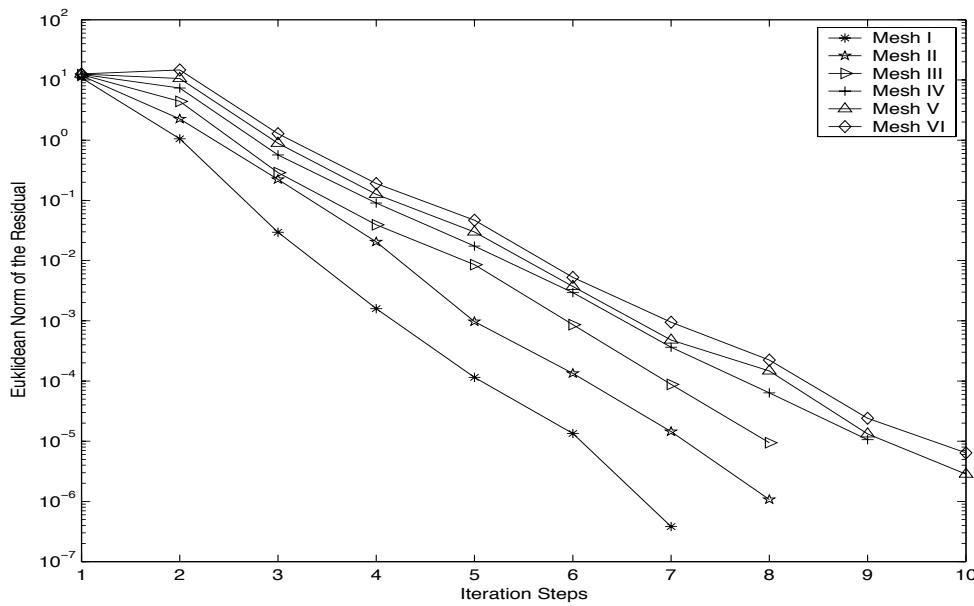

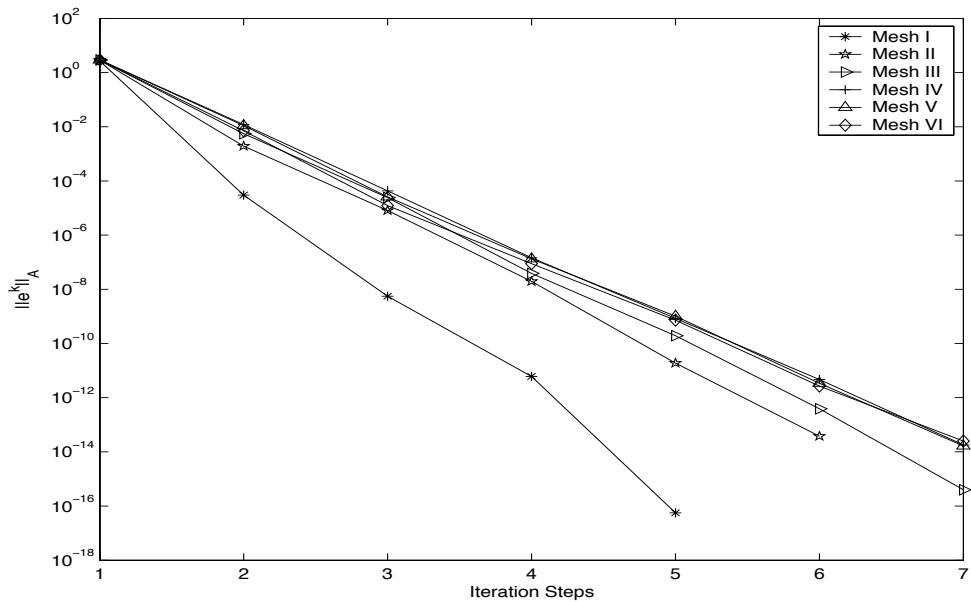

Figure 16: Convergence of the error in the energy norm ($m=1, n=1, \tau=1, ms=1$).

 Figure 17: Convergence of the residual ($m=1$, $n=1$, $\tau=1$, $ms=1$).

 Figure 18: Convergence of the error in the energy norm ($m=5$, $n=1$, $\tau=1$, $ms=1$).

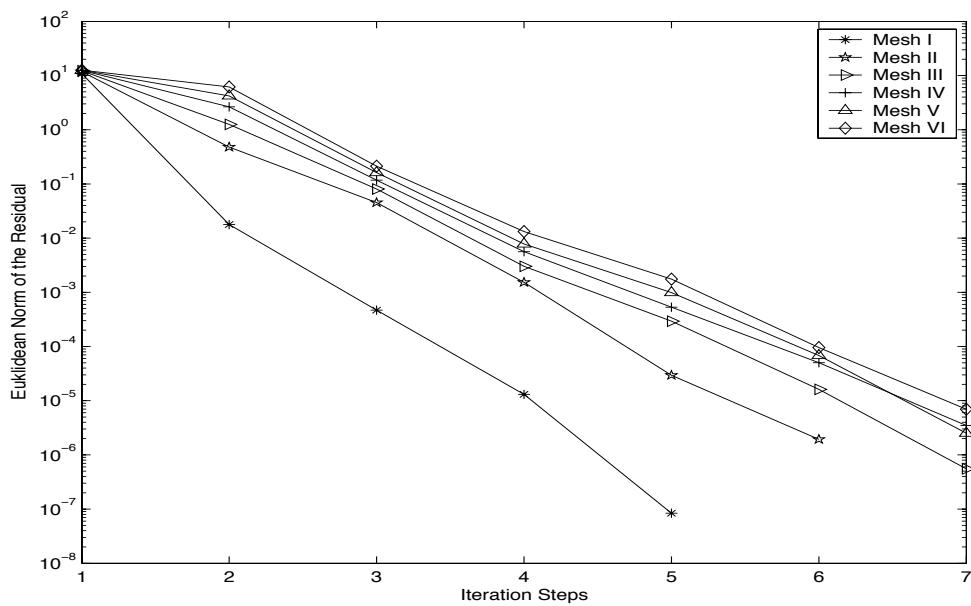

Figure 19: Convercenc of the residual ($m=5$, $n=1$, $\tau=1$, $ms=1$).

5.6 Stable Space Decomposition

To guarantee that the condition number of the preconditioned system is independent of the system size, the interpolation operator \mathcal{I} must fulfil:

$$\inf\{h^{-2}\|\tilde{v}\|_{L^2} + \|w\|_{A_0}^2 : \tilde{v} + \mathcal{I}w = v, \tilde{v} \in \mathcal{V}, w \in \mathcal{V}_0\} \lesssim \|v\|_A^2 \forall v \in \mathcal{V}.$$

This could be proved if an operator \mathcal{P} was found that satisfies:

$$h^{-2}\|v_h\|_{L^2}^2 + \|w\|_{A_0}^2 \lesssim \|v\|_A^2$$

with

$$v = v_h + \mathcal{I}v_0, v_0 = \mathcal{P}v, v_h = v - \mathcal{I}\mathcal{P}v.$$

Numerical experiments reveal that this is not the case, if nodal interpolation operators are used for \mathcal{I} and \mathcal{P} .

Figures 20 and 21 show the dependence of μ and λ on the (relative) mesh size h for the family of test meshes.

$$\|v - \mathcal{I}\mathcal{P}v\|_{L^2} \leq \lambda(h) h \|v\|_A \quad (37)$$

$$\|\mathcal{P}v\|_{A_0} \leq \mu(h) \|v\|_A \quad (38)$$

In these experiments, μ and λ are definitely not constant and therefore, inequalities (17) and (16) are not fulfilled.

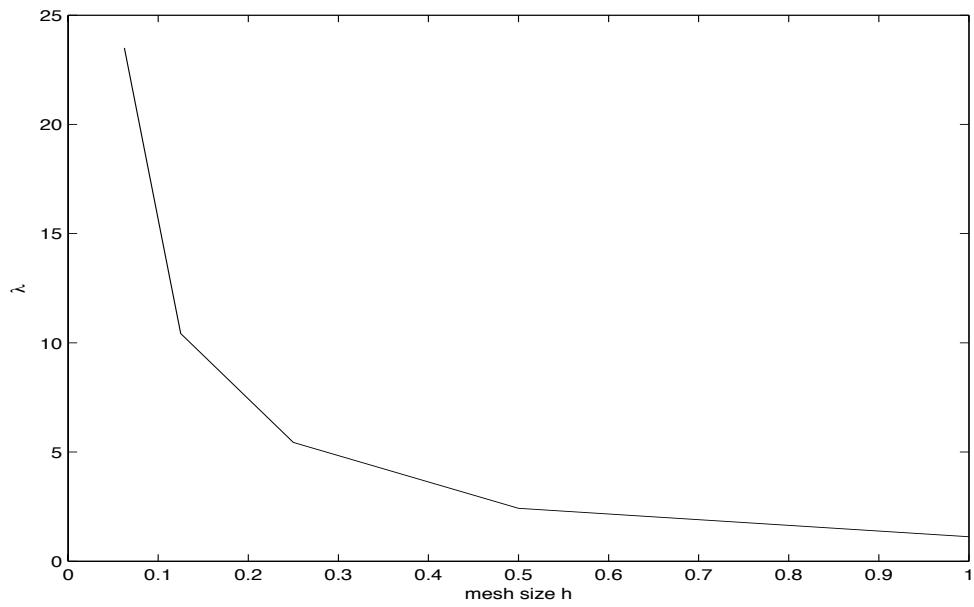

Figure 20: Dependence of λ on the mesh size h .

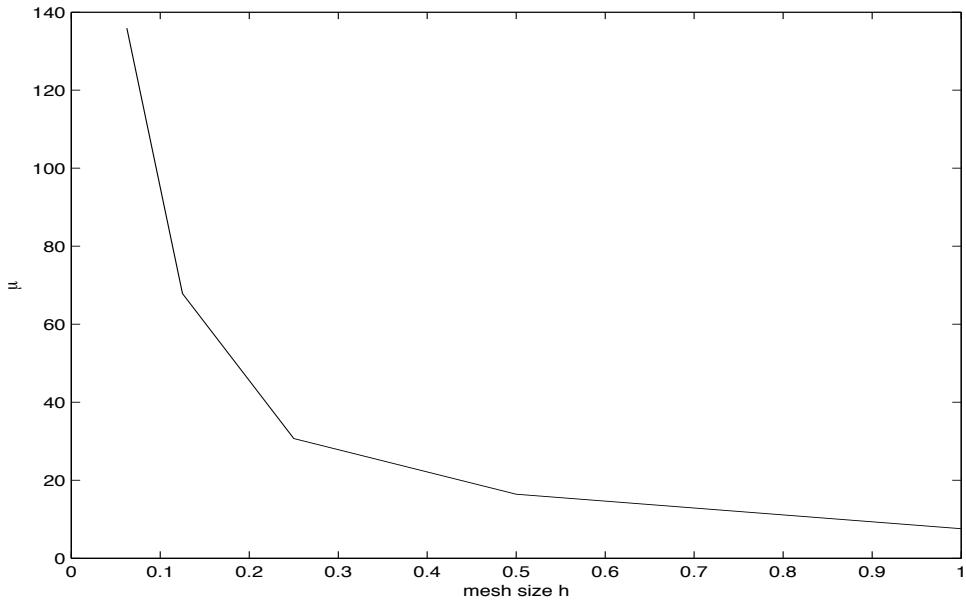

Figure 21: Dependence of μ on the mesh size h .

6 Conclusions and Outlook

In this diploma thesis, an auxiliary space method for edge elements has been implemented to precondition the linear system arising from Maxwell's equations. The computational costs of all parts of the algorithm scale linearly with the system size and for the right hand side function used in the numerical experiments, the number of CG iterations is (almost) independent on the system size. Thus, for this specific problem, with a right hand side function that changes slowly in space, the costs to solve the problem also scales linearly with the system size. However, the condition number shows a slow logarithmic growth, so there will probably be cases where the number of CG iterations will increase when the mesh is refined. The reason for this is assumed to be the insufficient interpolation operators \mathcal{I} and \mathcal{P} that allow no stable decomposition of the space. Since the other parts of the algorithm seem to fulfil the conditions for a linear scaling of the method, the challenge now will be to find better interpolation operators to link the original with the auxiliary space.

7 Acknowledgement

I would like to thank Prof. R. Hiptmair for the proposition of this diploma thesis and his support in numerical and analytical mathematics.

Furthermore, I want to acknowledge the staff from the IT support group for their assistance in computer matters.

Special thanks go also to my diploma colleagues E. Kunz and C. Winkelmann for the fruitful discussions and the good working atmosphere.
