Summary of the situation:

- Europe records a 5.3% growth rate of confirmed infections today compared with 4.8% yesterday, with outbreak progress in medium scenario decreasing from 69.1% to 68.2%, due to the up-adjusted estimated final total confirmed cases in the medium scenario to 1.09 million today. It seems that Europe has passed its inflection point[1] recently, with a converged estimated distribution of final number of total confirmed cases per million. However, it is important to understand that confirmed infections undershoot actual infections by a very large margin. Figure 1 allows us to suggest that all rich cool north[2] countries are converging except Sweden, while hot north[2] and S hemisphere[2] countries are not. The fact that Europe taken as a whole is not in the middle of the distribution (Figure 1) is mainly due to the weight of Russia on the average, which has only 69 confirmed cases per million population.

- The number of total confirmed cases exceeds 400K today in the US (8.4% growth from yesterday). The epidemic in the USA is both geographically diverse and at an early stage, so the uncertainty is still huge for the future developments. Readers can refer to Supplements to COVID-19 Confirmed Cases Prediction (April 7th, 2020)[2] for our analysis on the US test numbers and the confirmed case numbers.

- The daily confirmed cases in Austria is 329 today, compared with 343 yesterday, which is within our prediction range of yesterday. As shown in Figure 2, our prediction is more accurate compared to earlier when we tended to underestimate, this is because the situations become mature in more countries and thus the Logistic models become more reliable. In addition to the four early stage countries (Turkey, Brazil, Sweden and Japan), we also underestimated UK and Netherlands, which are still floating around the peak of the daily incidence curve.

- Spain, Switzerland, Belgium, Italy, Germany, Portugal, and France continue to present the signs that inflection points have been passed, with decreasing growth rate and converged (but sometimes dispersed) distributions of the final confirmed cases. However, more data is needed to confirm that the epidemic is in an after-peak trajectory and it is still possible that they may resume their previous exponential growth, while the warmer weather may make this scenario less likely (unless of course it becomes colder again). Confirmed cases are a leading indicator while deaths are a lagging indicator and we anticipate that daily mortality numbers may begin to fall ~ 2 to 3 weeks after the peak in new confirmed cases.

- Brazil, Sweden, Turkey and Japan continue their previous exponential growth, indicating highly uncertain future scenarios, as shown by their non-converged ensemble distributions of final confirmed cases (Figure 1). The transmission in Japan seems to accelerate as do reported deaths, but the death rate seems to have reversed again raising questions about the reporting standard. Unraveling the epidemic in Japan remains a work in progress.

-The irregular dips and spikes in the data most likely reflect data aggregation and reporting delays where numbers not included one day are included in the following day.

---

[1] On a logistic curve, the inflection point indicates where the curvature changes its sign. As we model the total number of confirmed cases, it is equal to the peak of the daily increase curve, after which the daily number of cases is decreasing. If the inflection point has been passed, the worst of the outbreak is over.

Method:

This report updates predictions for the number of COVID-19 confirmed cases at four time horizons (1-day, 5-day, 10-day and end of the outbreak) and for various countries/regions, based on a phenomenological approach detailed in [1]. We employ 3 versions of the generalized logistic growth equation to model the total number of confirmed cases, resulting in a positive, medium and negative scenario for the final expected number of cases. Note that, for countries/regions at early growth stages, the predictions for long-term horizon (10-day and end of the outbreak) are highly uncertain and will vary a lot as the situation changes. The predicted ranges overlap and, as time passes, we anticipate our methodology to zero in on more reliable numbers.

Data source: European Centre for Disease Prevention and Control (ECDC) [2] updated every day at 1pm CET, reflecting data collected up to 6:00 and 10:00 CET. Thus the daily data in some countries is one day delayed compared to other online live sources.

Key Figures & Tables:

-In Table 1, we report the latest confirmed cases per million population and the estimated outbreak progress in the positive and medium scenario (today's confirmed cases divided by the estimated total final confirmed case in positive and now additionally in medium scenarios).

-In Table 2, we report the prediction results in each selected country/region at four time horizons (1-day, 5-day, 10-day and end of the outbreak) in three scenarios. The detailed fitting results for each country/region are plotted in the figures at the end of this report.-

-In Figure 1, we present a distribution of the estimated final total confirmed numbers per million population based on the positive and medium scenario.

-In Figure 2, we show the 1-day prediction error of yesterday's report.

Comment: We need to emphasize that reported confirmed cases are a leading indicator that is subject to a large number of extraneous variables such as sampling rate[3], sample targeting and reliability of testing. See note at end of this report. The real number of cases in the population is likely to be many multiples higher than those computed from confirmed tests. We strongly recommend that national governments should publish the number of daily tests and implement random testing (polling) in the population, to facilitate all modeling work and therefore better understanding of the epidemic to help guide appropriate policy responses.

[3] For instance, The UK is experiencing issues with raising the testing rate linked to a global shortage of certain key reagents and swabs. From since April 1st, all testing is to be targeted at health sector staff and this will obviously bias future data compared with past data.

Table 1. Current confirmed cases per million population and estimated outbreak progress in positive and medium scenarios (today's confirmed cases divided by the estimated total final confirmed cases in positive and medium scenario). Numbers in brackets are 80% confidence intervals. As positive scenarios predict a smaller final number of total infected cases, the outbreak progress is thus larger in the positive scenario. Note that the estimated final confirmed numbers tend to underestimate the final results, thus the estimated outbreak progress serves both as a lower bound for future developments and as a guide of the dynamics of the evolution of the epidemics[4]. The number of tests per million population and confirmed cases per test are presented in the last two columns based on the information from Wikipedia [3].

	Confirmed per Million Population (Apr-09)	Outbreak Progress in Positive Scenario	Outbreak Progress in Medium Scenario	Tests per Million Population (update date in brackets)	Confirmed Cases per Test (update date in brackets)
Spain	3140	98.5% (93.1%, 104.0%)	82.0% (77.9%, 86.5%)	7596 (Mar 21)	5.6% (Mar 21)
Switzerland	2667	90.4% (84.8%, 97.1%)	81.2% (74.7%, 87.8%)	19536 (Apr 07)	12.9% (Apr 07)
Italy	2307	99.7% (94.3%, 106.2%)	81.8% (78.5%, 85.5%)	14148 (Apr 09)	16.3% (Apr 09)
Belgium	2049	75.4% (66.6%, 83.1%)	71.9% (62.3%, 81.3%)	7316 (Apr 07)	24.7% (Apr 07)
Austria	1466	94.9% (88.7%, 101.4%)	94.1% (89.0%, 99.6%)	14185 (Apr 09)	10.3% (Apr 09)
United States	1321	64.1% (53.6%, 73.3%)	57.2% (46.9%, 66.0%)	6822 (Apr 08)	17.8% (Apr 08)
Germany	1305	83.6% (78.5%, 88.7%)	76.4% (70.1%, 82.4%)	15850 (Apr 05)	7.0% (Apr 05)
Portugal	1278	79.6% (72.5%, 87.3%)	76.9% (68.4%, 84.4%)	12760 (Apr 08)	9.5% (Apr 08)
France	1225	82.8% (74.8%, 91.2%)	77.0% (67.5%, 87.2%)	3346 (Apr 02)	25.4% (Apr 02)
Netherlands	1193	93.5% (87.8%, 100.2%)	71.6% (65.4%, 76.8%)	5827 (Apr 08)	19.3% (Apr 08)
Europe	996	79.9% (76.0%, 83.7%)	68.2% (64.2%, 72.2%)	NA	NA
United Kingdom	913	60.0% (50.5%, 67.9%)	56.5% (45.3%, 65.7%)	3445 (Apr 08)	23.7% (Apr 08)

Iran	790	Not reliable	Not reliable	2538 (Apr 07)	28.7% (Apr 07)
Turkey	464	67.5% (55.2%, 78.9%)	25.1% (0.0%, 48.4%)	3323 (Apr 09)	13.8% (Apr 09)
South Korea	202	Not reliable	Not reliable	9231 (Apr 07)	2.2% (Apr 07)
Brazil	76	Not reliable	Not reliable	261 (Apr 02)	12.5% (Apr 02)
Japan	38	Not reliable	Not reliable	487 (Apr 08)	6.9% (Apr 08)

[4]One uncertainty with Italy (and other countries) is whether the main outbreak that is focused on the North may spread through other parts of the country. In other words, does the dynamics aggregated over a whole country represent correctly the dynamics in different parts?

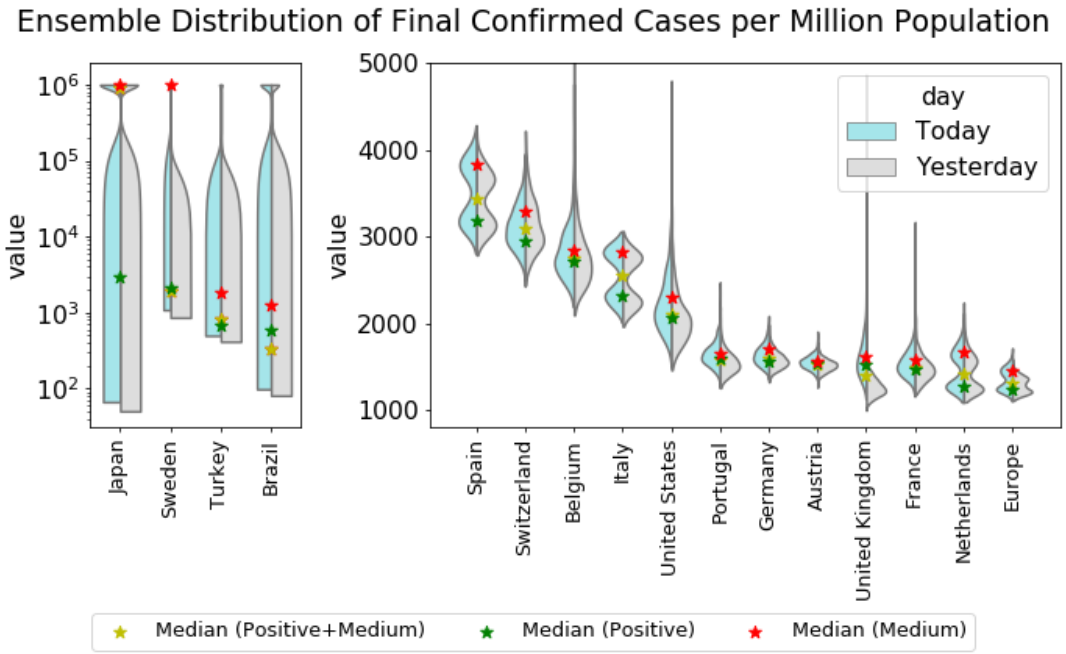

Figure 1. Violin plot of the distributions of the final total number of confirmed cases per million derived by combining the distributions of the positive and medium scenarios. The left side of each violin in cyan is today's distribution, while the right side of each violin in grey is yesterday's distribution. The model setup in the negative scenario does not incorporate a maximum saturation number and thus cannot be used. The yellow star indicates the median prediction for the combined distribution, while the green and red stars indicate the median of the positive and of the medium scenarios respectively. Note that, where we have >1 million infections per 1 million of population, the results are deemed to be unreliable (Table 2).

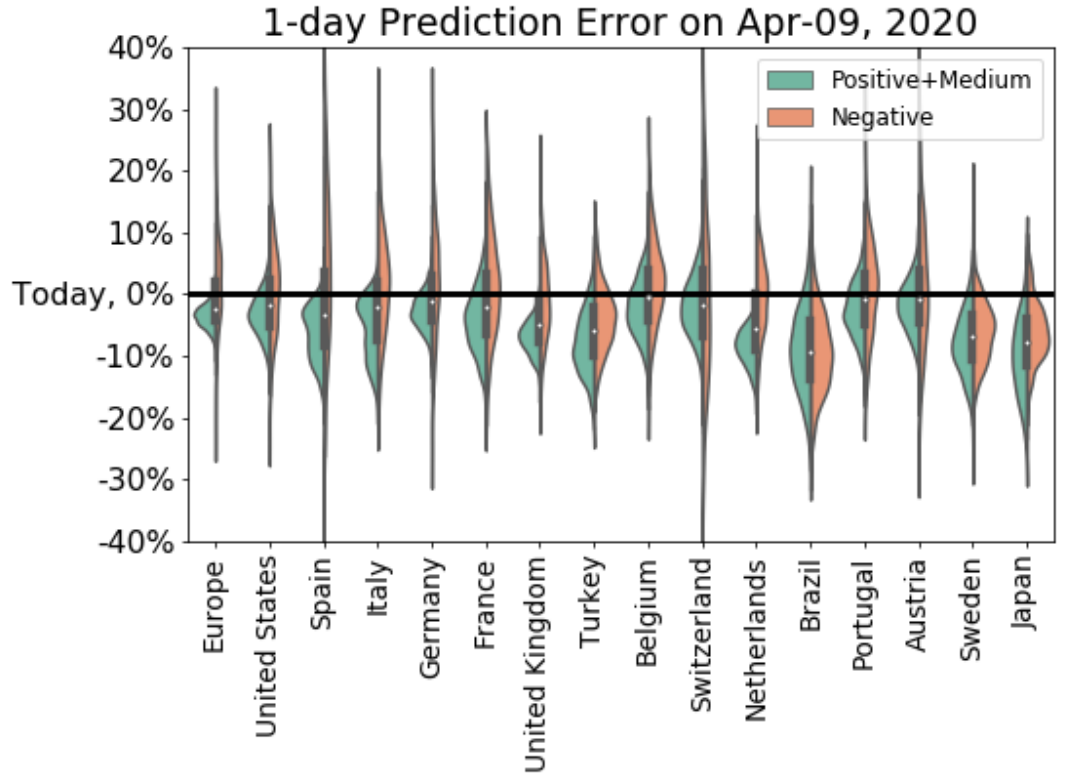

Figure 2. One-day prediction error of the 13 countries/regions. The horizontal line corresponds to today's empirical data. We show the full distribution of errors for each of the two scenarios.

Table 2. Predictions for the number of confirmed cases at four time horizons (1-day, 5-day, 10-day and end of the outbreak) and for various countries/regions. The values in parentheses are 80% prediction intervals based on 500 simulations using a negative binomial error structure. In Today's validation column, today's empirical data is presented below yesterday's 1-day predictive interval. "Not reliable" is declared if more than 10% of the simulations produce extreme numbers (larger than total population). All numbers are in thousands.

Country	Scenario*	Today's validation	10-Apr	14-Apr	19-Apr	Final Total Confirmed
Europe	Positive	(694, 731) 743	743 (721, 766)	825 (797, 853)	882 (848, 918)	930 (888, 978)

	Medium	(60.4, 67.2) 64.6	64.3 (60.9, 68)	73.7 (69.7, 79)	84 (77.7, 93)	Not Reliable
	Negative	(62.4, 70.9) 64.6	68.9 (64.7, 73.9)	82 (76.6, 87.7)	100 (93, 107)	Not Reliable

* Note:

-The scenarios are based on the final total confirmed numbers. The positive and medium scenarios are derived from the Generalized Logistic Model and the Logistic Model. The model with the lower mean predicted final total confirmed number K is classified as the positive scenario, and the other one is classified as the medium scenario. The negative scenario is based on the Generalized Growth model, which should only describe the early stage of the epidemic outbreak and is therefore least reliable for countries in the more mature stage.

-Trajectories from Iran have largely deviated from a typical logistic type growth (S curve), and can't be properly described by our models. Although we still report its calibration results in Table 1, they should not be taken as reliable in all scenarios and time horizons. This is probably a result of unreliable reported data from Iran.

Limitations of using the statistics of reported confirmed number

It is important to understand what our prediction models show. The predictions are based on cases identified on the basis of testing and they therefore predict the numbers of future positive tests. Relating positive test results to real levels of infection is subject to a large number of biases. It is a fact that the real number of infections is far higher than those recorded in positive tests since only a tiny fraction of any population has been tested. It is also the case that, in most countries, testing is biased towards those who think they are infected. The first bias, therefore, will underestimate the real number of infections while the second bias will tend to overestimate since it is biased towards those who think they are ill.

There are further complications. Depending on the testing protocols used, in some instances false positive results have been obtained. In other words, someone without the disease tested positive, probably because they were infected with some other coronavirus. And in other cases, false negative results were obtained, as was the case with the early testing deployed in the USA.
One final complication is the fact that tests are conducted sequentially over time. They do not represent a snapshot of a day in time. Many of those tested early, giving a negative result, may today get a positive result. And many, who tested positive early on, may today be cured.
We anticipate that, over time, our methodology will improve and will provide a more accurate picture of the true levels of infection and where they are headed.
